CAUSES OF BLINDNESS IN MINNESOTA*

CHARLES E. STANFORD, M.D.

Minneapolis, Minnesota

THE factors responsible for blindness in the group applying for financial aid as needy blind have been studied to determine how much blindness is possibly preventable or remedial.

The examination of the applicants was done by those practicing ophthalmology in the various cities throughout the state. It is therefore through the coöperation of these physicians that these data have been secured.

Causes of blindness may be classified in several ways. Of most importance from the prevention of blindness viewpoint is an etiologic grouping of causes, while from a remedial aspect the descriptive or anatomic classification is of most value.

At the time this study was made there were 768 detailed records available. That number is now somewhat larger, but the percentages are affected very little. Only cases considered eligible for aid from a visual standpoint were included.

ETIOLOGIC FACTORS IN BLINDNESS

	Cases	Per Cent
Infectious diseases	241	31.3
Trauma	104	13.5
Toxic poisoning	3	.4
Neoplasms	16	2.0
Non-infectious systemic diseases	43	5.4
Congenital and hereditary origin	176	22.9
Etiology undetermined or not specified	185	24.
	768	100.

Each of the above groupings can be broken down as follows:

*From the State Bureau for Aid to the Blind and the Department of Ophthalmology, University of Minnesota. Read at the annual meeting of the Minnesota State Medical Association, Rochester, Minnesota, April 24, 1940.

Infectious Diseases

	Cases	Per Cent
Gonorrhea	2	
Measles	6	
Meningitis	10	
Ophthalmia neonatorum	37	4.7
Septicemia	1	
Focal sepsis, etc.	12	
Syphilis—prenatal	10	7.4*
Syphilis—acquired	47	
Syphilis—clinical diagnosis only	27	
Scarlet fever	1	
Trachoma	19	2.4
Ocular tuberculosis	11	
Other infections specified	13	
Infectious causes, type not specified	40	

*Syphilis (prenatal, acquired and clinical diagnosis only) as a group, form 10.9 per cent of cases.

*Trauma**

	Cases	Per Cent
Non-industrial injuries	56	7.3
Industrial injuries	48	6.2
Types of non-industrial accidents		
Injuries at play and sports	33	4.1
Household activities	4	
Street and traffic	3	
Birth injuries	2	
All others	14	

*See sympathetic ophthalmia—topographic classification.

Non-Infectious Systemic Diseases

	Cases	Per Cent
Anemia	1	
Diabetes	11	1.4
Nephritis	1	
Vascular diseases	8	
Central nervous system diseases	4	
Disorders of pregnancy and labor	9	1.2
Other systemic diseases—specified	5	
Other systemic diseases—not specified	4	

Congenital and Hereditary Factors

	Cases	Per Cent
Congenital	83	10.8
Known hereditary	43	5.8
Hereditary origin—presumed†	46	6.1
Consanguinity	1	
Not specified	3	

†Eye condition usually considered hereditary but for which, in these cases, the family history was negative.

Etiology Undetermined

	Cases	Per Cent
Unknown to science*	114	14.8
Undetermined by physician†	49	6.4
Not specified	22	2.8

*Includes (1) Senile cataracts which might be otherwise classified as due to age changes, etc.; (2) Glaucoma; (3) Cases of optic atrophy known to have been studied exhaustively.

†Includes largely those cases, long blind, seen by examiner years after causative factor existed. Topographical diagnoses such as phthisis bulbi, optic atrophy, etc.

DESCRIPTIVE OR ANATOMIC CLASSIFICATION

Causes of Blindness—Topographic Classification

	Cases	Per Cent
Eyeball	219	28.5
Cornea	86	11.0
Iris and ciliary body	76	9.8
Crystalline lens	83	10.8
Choroid and retina	126	16.4
Optic nerve	174	22.6
Vitreous body	2	
Miscellaneous and ill-defined	2	
	768	100.

This larger grouping can be broken down to the following:

Eyeball

	Cases	Per Cent
Glaucoma	76	9.8
Refractive errors, chiefly myopia	31	4.
Developmental anomalies	33	4.1
Albinism	6	
Anophthalmos	3	
Megalophthalmos	5	
Microphthalmos	4	
Aniridia	4	
Colobomata	1	
Others—specified	6	
Others—not specified	4	
Disorganized eyeball (phthisis, etc.)	76	9.8
All others	3	

Lesions of the Cornea

	Cases	Per Cent
Interstitial keratitis	9	1.1
Keratitis—type not specified	13	1.7
Ulcerative keratitis	35	4.3
Pannus	15	1.9
Other affections specified	13	1.7

Iris and Ciliary Body

	Cases	Per Cent
Iridocyclitis	38	4.9
Iritis	4	
Sympathetic ophthalmia	34	4.2

Crystalline Lens

	Cases	Per Cent
Cataract*	79	10.3
Ectopia lentis	4	

*Includes 35 cases of congenital cataract.

Choroid and Retina

	Cases	Per Cent
Choroiditis	4	
Retinitis	13	1.7
Chorioretinitis	33	4.1
Detached retina	19	2.4
Central vessel occlusion	2	
Retinal degeneration	54	7.0
Other affections—specified	1	

Optic Nerve

	Cases	Per Cent
Optic atrophy	160	20.7
Optic neuritis	4	
Neuroretinitis	8	1.
Other affections	2	

INFECTIOUS DISEASES AND BLINDNESS

241 Cases

Ophthalmia neonatorum 37, syphilis 84, and trachoma 19, total 140 cases or 58 per cent of the blind in this group. Theoretically this 58 per cent (18 per cent of all blind) is entirely preventable blindness.

Ophthalmia neonatorum is now much less a cause of blindness than the above figure would indicate. The majority of those blind from syphilis are adults, affected in the fourth and fifth decades. Early and adequate treatment of primary syphilis could materially reduce this number. The trachoma group are largely among our Indian population. The incidence of the disease (trachoma) is considerably greater than the number of blind from it would indicate.

Of the forty-eight blind from industrial injuries 73 per cent are in the 21-49 year group.

Of the thirty-four classified as blind from sympathetic ophthalmia following injury to one eye, twenty-eight fall in the non-industrial group and of these nineteen were injured at play or in sports. It is an established fact that the most effective treatment for sympathetic ophthalmia is prevention. This means prompt and adequate care of all eye injuries no matter how apparently trivial they may seem. While blindness from this cause is infrequent in comparison with the total number of eye injuries, it is possible to eliminate it entirely.

Neoplasms caused blindness in sixteen cases, fourteen due to intracranial tumors. The average duration of blindness for these fourteen is seven years; in all cases vision was lost before operation was performed; in seven cases with visual changes as initial symptom a proven diagnosis of pituitary tumor has been established. The duration of visual disturbances before diagnosis in five cases with adequate histories ranged from one to five years.

Glaucoma as a cause of blindness (seventy-six cases—9.8 per cent) is probably too low a figure due to the number of blind on old age relief. It is significant to note that the records show twenty-two cases neglected to seek adequate medical care, and that in practically all cases in which operations were done, these were performed so

TRAUMATIC FACTORS IN BLINDNESS

Non-industrial Injuries	Age at Onset of Blindness						
	0-1	2-9	10-14	15-20	21-49	50-64	Total
Play or sport	0	15	7	6	5	0	33
Household accidents	0	2	0	1	1	0	4
Street and traffic	0	0	1	1	1	0	3
Birth injuries	2	0	0	0	0	0	2
Others specified	0	0	2	4	6	1	13
Others—not specified	0	0	0	0	0	1	1
Totals	2	17	10	12	13	2	56

late in the disease that very little vision was saved. Both the public and the physician must become more aware of the early symptoms and signs of this disease before the number of blind from glaucoma can be materially reduced.

Cataracts as primary causes of blindness, aside from the thirty-five due to congenital and familial factors, were recorded in only forty-four cases. This low figure is in part due to the number on old age relief and in part to the excellent surgical care that has been rendered to these people throughout the state. The majority of the forty-four cases are inoperable due to complications. A few have had complications during or after operation or have retinal or optic nerve changes as well.

A review of the cases blind from complications of non-infectious systemic diseases illustrates very well the participation of the eye in systemic disease and the need for careful eye examinations by physicians in all types of disease. Prevention of blindness from these causes, anemia, diabetes, nephritis, vascular disease, etc., must come from careful control by the physician with intelligent coöperation by the patient.

After careful analysis of 768 cases of blindness as to cause, age of onset, and degree of visual acuity, and realizing that little or nothing can now be done to restore vision to these people, the thesis "prevention of blindness" comes home with considerable force. Possibilities in prevention are:

1. A parentage free from serious familial eye disorders.

2. In instances in which an offspring of apparently normal parents has a serious eye defect, present at birth—and commonly familial—limitation of the number of further offspring is indicated. The occurrence of from two to six siblings, blind at birth, as illustrated in this report, is inexcusable.

3. Routine Wassermann tests on *all* expectant mothers and prompt institution of anti-syphilitic therapy in all mothers with positive reactions will reduce the number of blind from "congenital syphilis."

4. Continued use of the "Crede" method for prevention of ophthalmia neonatorum is imperative. Ophthalmia neonatorum now means that either the drops were not used or were inadequately used.

5. Blindness from trauma could be materially reduced. Most of our industrial accidents occur among independent workers and farmers upon whom no safety rules are imposed. Neglect of minor injuries until serious complications arise causes a large percentage of the cases of monocular blindness in this group.

The non-industrially blind are largely the result of thoughtlessness and chance-taking acts of childhood and youth. Prompt care of all those so injured may prevent many cases of blindness.

6. Inflammations of the iris and ciliary body (iritis and iridocyclitis) may be due to a variety of causes. The number of blind from this cause could possibly be reduced by: (1) more prompt seeking of medical advice by the patient; and (2) earlier diagnosis and intensive therapy.

7. Glaucoma—prevention of blindness from this cause depends entirely upon *early* diagnosis and prompt institution of treatment plus a thorough understanding by the patient of the need for continuing under observation and therapy.

All measures intended for a betterment of the public health are, therefore, an integral part of a prevention of blindness program.

GLAUCOMA*

ANDERSON C. HILDING, M.D.

Duluth, Minnesota

THIS brief talk has been planned to help physicians who are not eye specialists in recognizing glaucoma. It is not meant for ophthalmologists.

Every year many patients lose vision more or less completely from glaucoma. In many the vision might have been retained had the condition been recognized in time and proper treatment instituted. In general, it may be said that vision lost through glaucoma cannot be regained. It can also be stated that when glaucoma is recognized, visual loss can usually be prevented.

Glaucoma is a symptom and not a disease. It is an obstruction and like some other obstructions is dangerous. The causes are many and variable, some known and more or less completely understood, while others are poorly understood, and some causes probably remain completely unknown.

At the risk of over-simplification, we shall consider glaucoma as due to obstruction of aqueous drainage at the filtration angle. There is much more to it than this, but such a theory is practical for our purpose, and we simply haven't time to go into other factors, such as rigidity of the sclera, swelling of the lens, congestion of vascular beds, abnormal chemistry, or over-production of the aqueous humor, and so on.

The physiology of the aqueous circulation is briefly and simply about as follows. The aqueous humor is produced in the region of the ciliary body. It circulates through the interior of the eye, bathing and nourishing the vitreous body and lens. It then passes forward through the pupil into the anterior chamber where it enters a convection eddy. It leaves the eye through the filter in the pectinate ligament, which is located just anterior to the root of the iris, passing into the canal of Schlemm and thence back into the venous circulation.

When the outflow of aqueous humor from the filtration angle is obstructed, it accumulates within the eye, and the intraocular pressure (spoken of as tension) rises. This might occur from fouling of the filter by floating particles. It might also occur if the root of the iris should make contact with the posterior surface of the cornea, and overlie the filter through any considerable part of the circumference, as sometimes happens. Both factors might act together to impede drainage of the aqueous humor.

Increasing the intraocular pressure materially above normal has several very serious effects. The weak spot in the eyeball, where the nerve head enters, gives way to a certain extent, and the nerve head becomes pushed back, forming the so-called glaucomatous cup. This, in turn, subjects the nerve fibers in the nerve head to abnormal pressure and to certain tensions. They apparently become stretched across the non-yielding edge of the scleral ring about the nerve head. This blocks certain fibers and bundles of fibers, and the resulting loss of function produces various types of geometric scotomata. These are called neuroscotomata. Another effect of the increased pressure is a reduction in blood supply to the retina. A large part of the retinal blood supply enters the eye through the ophthalmic artery at a normal systolic pressure, variously estimated at between 65 and 80 mm. of mercury. The normal intraocular pressure is in the neighborhood of 25 mm. Given a normal blood pressure of 70 and a normal intraocular pressure of 25, the effective pressure at which the blood enters the eye on the crest of the systolic wave would be 70-25 or 45 mm. Should the intraocular pressure increase to 50 and the blood pressure remain the same, then the effective pressure remaining for the nutrition of the retina would be reduced to 20 mm. at the crest of the systolic wave. Further, there is probably an interference with the return of tissue fluid into the venules. Whether reduced blood volume or interference with return circulation of tissue fluid is more important does not concern us now. The fact remains that the retina is deprived of sufficient nutrition, and function is interfered with or lost. The result in the visual field is concentric contraction and certain branching scotomata called angio-scotomata. You will recall that the retina embryologically is a portion of the

*Read before the annual meeting of the Minnesota State Medical Association, Rochester, Minnesota, April 24, 1940.

brain. Like the brain, when its cells or fibers are destroyed, they are not restored. When retinal nerve fibers and cells are destroyed through pressure or lack of nutrition, or both, they are not replaced, and their function is lost forever. Therefore, we say that, in general, vision lost through glaucoma is not recovered.

There are three types of glaucoma ordinarily recognized, namely, primary, secondary, and congenital. We shall confine ourselves to the primary.

Primary glaucoma is subdivided in classification into "congestive" and "non-congestive" or "simple." The congestive in turn is subdivided into acute and chronic. The non-congestive is always chonic.

Acute congestive glaucoma occurs in attacks of more or less violence. Before the patient suffers much there is usually an extended period of minimal prodromal attacks. These are characterized by redness, some discomfort, and temporary reduction in vision. Eventually there comes a real attack, when the patient suffers one of the severest pains known to man. This pain is in, about, or back of the eye and radiates through the entire side of the head. The eye is red, lacrimation is increased, every light has a halo about it, and vision is greatly reduced. If severe enough, nausea, vomiting, and chills may result. Sometimes precious time is lost, while other causes for these symptoms are sought. When the physician arrives, he finds: (1) marked scleral congestion; (2) lacrimation; (3) shallow anterior chamber; (4) a steamy or cloudy cornea which is anesthetic (if the intraocular pressure is high enough); (5) pupil in mid-dilation and reacting poorly; (6) increased intraocular pressure. The first five of these symptoms are more or less familiar to all of you and can be readily recognized. I know of no good reason why the last—intraocular pressure—could not also be more familiar. You all test surface cellulitis for fluctuation in search of accumulations of pus. The technic of testing ocular pressure is the same. If one can readily feel fluctuation in an eyeball, the pressure is probably normal. If the eye feels hard, and slides about like a marble under the lid, the pressure is high. If it is not hard, but on the other hand you cannot be sure of fluctuation, the pressure may be and probably is moderately elevated. Try it on your own eyeballs with both forefingers. In order to be sure that you are palpating the sclera and not the cornea, which is important, turn your eyes well downward.

The treatment of glaucoma is instillation of miotics, some drug or drugs which have the property of contracting the pupil, thus drawing the root of the iris out of the filtration angle as far as possible. A solution of 1 per cent pilocarpin nitrate (or hydrochloride) is a very good and practical preparation. It can be instilled every ten or fifteen minutes for several hours until the attack subsides. Operation for the purpose of producing an artificial drain or filter or for removal of a portion of the iris at the root may later be necessary.

Differentiation between iritis and congestive glaucoma is important. The former calls for atropin to dilate the pupil. To instill atropin in acute glaucoma is a fatal mistake. Some years ago I saw a patient with acute congestive glaucoma in whom a mistaken diagnosis of iritis had been made, and atropin had been instilled. When I arrived, the pupil was in extreme dilation and the patient in extreme pain. Fortunately, the retaina had not yet been destroyed, and the situation was saved by operation. The patient has a useful eye after twelve years, but the pupil still remains in complete dilation. The best points in differentiation lie in the iris. In glaucoma the iris looks almost normal, and the pupil is dilated; whereas in irititis the iris markings are blurred because of swelling, and the pupil tends to contract. In irititis congested vessels can often be seen in the iris itself, and adhesions may be found between the pupillary margin and the lens. If you cannot be sure of the diagnosis, it is better to instill hypertonic salt solution or Lewis's solution, or do nothing at all until consultation with an ophthalmologist may be had. Fortunately, when acute glaucoma is severe enough to seriously damage the retina, the patient is in such extreme pain that both patient and physician do something about it.

Chronic congestive glaucoma simply consists in a progression of the acute attacks to the point where the intraocular pressure doesn't return to normal between attacks. The attacks continue to recur with more or less severity.

Simple non-congestive glaucoma is much less severe than the congestive type but, because of its insidious onset and progress, may be much more dangerous from the standpoint of eventual

visual loss. It is about ten times as frequent as the inflammatory. You meet it much oftener in your practice and probably miss it usually. This is because it is so frequently entirely symptomless. One is almost at a loss in advising what steps should be taken by way of precaution.

Doubtless the ophthalmologist also misses some cases. He picks up many in routine refractions by palpating the eyeball or measuring the intraocular pressure. I dismissed a patient from the hospital just last week whose glaucoma had been found in the course of routine refraction. When he came in requesting refraction he had no suspicion that there was anything other than refractive error present. The tonometer revealed increased intraocular pressure in both eyes—left greater than right. When put on treatment with miotics, the right eye responded nicely, but the left eye tended to maintain an elevated pressure and loss of visual field continued progressively. The left eye was therefore operated upon.

Some times the ophthalmologist can only suspect the presence of glaucoma even after a complete examination with the special diagnostic methods in his office. He may then resort to certain provocative tests. Even with no symptoms and minimal signs, glaucoma may be well established already. It seems to me that many of these symptomless cases must inevitably continue to be missed by the family physician, even though he may see the patient from time to time for other things.

When symptoms begin, they consist of: (1) reduced vision; (2) scotomata; (3) reduced dark adaptation; (4) reduced color sense, but no redness or lacrimation. By the time the patient is aware of these symptoms, retinal damage may already be considerable. Such patients go seeking a pair of glasses. It is the responsibility of the examiner to discover the true nature of the difficulty. One of the most serious indictments of the indiscriminate fitting of glasses lies in the fact that glaucoma at this stage, when most of the vision can still be saved, is so frequently missed. Unless the refractionist is competent to recognize early glaucoma, it is inevitably and invariably missed. Later when it is so advanced that useful vision is already largely gone, it is often suspected for the first time that there is something other than refractive error affecting the eye.

If you examine the eyes of such a glaucoma patient who has minimal symptoms you will find that the pressure is elevated in both. Simple glaucoma is bilateral, although the pressure is usually greater in one eye. The anterior chamber is shallow. The pupil is normal or dilated. Fundus examination reveals a glaucomatous cup in the nerve head. You may be able to tell that the visual field is contracted by rough tests even without a perimeter.

By special tests the ophthalmologist finds in addition: (1) free pigment in the anterior chamber; (2) adhesions in the filtration angle between the iris and the posterior corneal surface; (3) atrophy of the iris; (4) atrophy about the disc in the fundus; (5) on the perimeter, visual field alterations both as to form and color, and scotomata.

The treatment again is pilocarpin, eserine, or some other miotic. If this controls the pressure well, and if the patient can be depended upon to use the drops, no operation is necessary.

The patient must realize, however, that his eyes must be treated for the rest of his life. Some patients begin in all seriousness but some times become careless and neglectful. To illustrate. A 60-year-old carpenter from a nearby city came in on account of reduced vision in the right eye. That was in 1925. A study revealed simple glaucoma that could be fairly well, but not completely, controlled with miotics. Operation was advised, but he refused, so he was carefully instructed in care of the eye, and dosage was carefully adjusted for him. He continued treatment for a while but after a time became careless, did not return for check-ups, but instead had several changes of glasses. Seven years later he returned with pain and redness in the right eye, which had, meanwhile, become entirely blind. The pressure was found to be about 80. The left eye was also definitely glaucomatous, but this time the patient consented to operation, and the second eye was saved.

In a short discussion of this nature it is not possible to say a great deal about glaucoma, but it is hoped that after this little review you may suspect the trouble more often and help to save the vision of these patients who mistakenly assume that they only need a change of glasses. If any of your patients over thirty-five years of age complain of reduced vision or blind spots, keep these few things in mind: Glaucoma oc-

curs in the latter half of life, and untreated glaucoma leads to irreparable blindness, usually with no pain and with but few symptoms. Don't tell your patient that this reduced vision is due to age. Visual acuity remains unaltered to advanced age unless pathological conditions arise within the eye. Don't tell him that it is due to cataract and that he may postpone treatment until his vision is reduced to counting fingers even though he may have signs of cataract. Most glaucoma patients also have cataracts. Don't send him out to change his glasses merely, but insist upon a competent and thorough examination. If you can recognize, or even suspect, glaucoma, you will have rendered your patient an inestimable service. For him, it may mean the difference between vision and blindness.

SENILE CATARACT*

E. W. HANSEN, M.D.

Minneapolis, Minnesota

WHEN a person is told that there is a cataract developing in one or both eyes, he often throws up his hands in horror. How often some member of the family, or even the family physician, when an elderly person comes for an eye examination, warns the ophthalmologist not to tell the patient there is a cataract, if one is present. "Anything else but that," they say. If the truth were known, "anything else but" is a much more serious condition than uncomplicated cataract formation.

One should be very sure, in the first place, that any progressive loss of vision in an elderly person is due to lens changes. We see people who haev been told that they had cataracts and must wait until they are "ripe." When they come for operation, they are almost or entirely blind, not from cataracts, but from a chronic simple glaucoma. Other serious lesions are those in the retina, circulatory changes, senile macula degeneration, arteriosclerosis and hypertension. Patients with cataracts, and the public generally, should be told that cataracts are not the most serious eye condition they can have, but belong at the other end of the scale, among the less serious. Almost all uncomplicated cataracts can be removed with relatively little discomfort to the patient and with resulting good vision.

Senile cataract is a name given to the change which occurs in the crystalline lens producing a hard and, eventually, opaque lens. It results from repeated insult to the lens structure by chemical, mechanical, thermal, photogenic, or nutritional factors. It is not merely a degenerative change taking place with increasing years, but a real pathological condition. While the greatest number of cases occur in patients who are around seventy years of age the same condition obtains in patients in the forties or even earlier.

A good deal of work has been done, much in the past decade, on the chemistry of the lens, and the experimental production of cataract. From this we know of chemical changes which take place in normal lens as compared with cataractous lenses, particularly an increase in cholesterin and in sodium and calcium salts, especially the phosphates, and a decrease in potassium. We see the changes which occur in lenses of diabetic patients, causing changes in refraction, and, in some, a rapid development of opacity, true diabetic cataract. In others we have a more slowly developing cataract, in every respect like the so-called senile cataract, which should probably be called senile cataract in a diabetic patient rather than diabetic cataract.

The lens has no blood supply, and its nutrition must be maintained by osmosis from the intra-ocular fluids which surround it. The capsule of the lens acts as a semipermeable membrane, allowing passage of nutriment into the lens and the discharge from the lens of the products of its metabolism. Any interference with this process causes the lens fibers to become opaque. Such a marked change in the balance of osmotic pressure takes place in diabetes, resulting in swelling and opacity in the lens.

Experimental work on lenses has shown that ultra-violet rays from the quartz mercury vapor arc, ordinary sunlight to a lesser extent, and

*Read at the annual meeting of the Minnesota State Medical Association, Rochester, April 24, 1940.

infra-red rays slightly, ionize lens material making the phosphate ions electronegative. By uniting with positively charged calcium ions in the lens, insoluble calcium phosphate is formed.

Other experimental work has shown that cataracts can be produced in animals by feeding lactose, and even more rapidly with galactose. It has been shown further that if vitamin C, and more especially, if cystine is added to the diet in these rabbits that there is an appreciable delay in the cataract formation. Galactose causes a diminution of the sulf-hydryls (glutathione and cystein) necessary to the oxidative and reducing process in the lens. The addition of yeast, rich in glutathione, of cystine alone, or of vitamin C, definitely stayed the process of opacification of endocrine dysfunction is well known.

We know that cataracts can develop from electric shock, from irradiation with x-ray and radium, in glass blowers, and more frequently in tropical countries where there are more ultraviolet rays in sunlight than in more temperate regions. The possibility of cataract development on an allergic basis, as seen in cases of more or less generalized eczema also should be mentioned. Cataract formation in various types of endocrine dysfunction is well known.

All this experimental and clinical evidence shows the effect on the lens capsule and on the lens substance. It seems very likely that the ordinary senile cataract is a cumulative result of one or of a combination of factors in the daily life of individuals whose lenses are subjected to repeated insults.

From this it can be seen that there may be a wide range in the age period when cataracts develop, and in the rate of progress of lens changes. The younger the patient and the slower the development, the more difficult is the handling of the case.

Up to the present time the medical treatment of cataract has been very disappointing. Many substances have been used such as drops, powders for insufflation, subconjunctival injections and internal medication. I do not believe I have ever seen a case in which I could be sure that the development of cataract was arrested by medical treatment, although various observers have reported arrested development and even clearing of opacities. I do know that it has been, unfortunately, a lucrative field for charlatans.

This does not mean that one should not treat the patient in whom cataracts are developing. The general health should be looked after, particularly hygienic and dietary factors. Dionin solutions may be used as drops instilled into the conjunctival sac. In the incipient and immature stages in those cases where the opacity is mostly central the pupil can be dilated during the daytime with a weak homatropine solution, allowing for some vision with the clearer peripheral portion. If this is done, the tension of the eye must be watched.

While the vitamins C and G (B) have been shown to have an influence in the formation of experimental cataracts, their use in treatment up to the present time has shown no definite results. They may be tried, however, especially in the very early stages of lens change, with some hope of influencing the morbid process. As the work in this field is continued, there is reason to hope that we will have a helpful agent in the combating of senile cataract, at least when seen in its early stages.

The most important consideration in the treatment of patients with senile cataract has always been surgery. Judgment as to time of operation must be exercised. If one eye remains useful, the more involved eye should not be operated in an immature state. If both progress about equally and the patient is incapacitated one cataract should be removed. If one eye goes over to hypermaturity while the other is still useful, the lens should be removed, depending on the age and condition of the patient. There are too many factors involved in this problem to permit further consideration in the short time we have.

In the pre-operative care of the patient, the general health should be built up as well as possible. Foci of infection, especially teeth, should be eradicated. While some surgeons feel that there is little danger from such foci when they have been present for some time I have a healthy respect for the damage that may be done by postoperative endogenous infection. I still believe the possibility of trouble is greater from these, than from infection in the conjunctival sac. The latter, however, should be cleaned up. An infected lacrymal sac should be removed. If the patient is a diabetic, the sugar should be reduced to a minimum.

As to the surgery itself little need be said. I believe that for the most part, the classic operation with removal of the lens from the capsule

is safer than the intracapular operation, if the surgeon does not do a great many operations. Arnold Knapp reported that vitreous loss was definitely greater in 500 intracapsular operations than in those receiving extracapsular extraction. His comment is as follows:

"The complication of the intracapsular operation which may be traced to the operative technic is a severe and definite form of iridocyclitis due to traction on the ciliary body. The greater number of cases of loss of vitreous with its complications can be reduced by better anesthesia and greater experience. Glaucoma is much less frequent than with the extracapsular operation. The question of the relative frequency of detachment of the retina is open. The dire late consequences after the intracapsular operation which have been repeatedly brought forward by some writers cannot be substantiated by facts."

Summary

1. Senile cataract is a disease of the crystalline lens and not merely a degenerative process of old age.

2. Medical treatment of this disease of the crystalline lens has been disappointing.

3. Experimental work on cataract formation is giving us hope of more satisfactory treatment of this common eye condition.

4. Cataract surgery, in otherwise uncomplicated eyes, is successful in most instances, and patients should not be left to live in dread of blindness or fear of operation.

SQUINT IN RELATION TO LOSS OF VISION*

H. W. GRANT, M.D.

Saint Paul, Minnesota

CENTRAL or macular vision begins to develop at the end of the second post-natal month and such development continues until the end of the sixth or seventh year. Vision is established after this age. The occurrence of squint before the normal and complete establishment of vision is accompanied by amblyopia or loss of vision in the squinting eye if the squint is monocular. Since amblyopia, or loss of vision, is common in convergent and rare in divergent squint, the discussion of amblyopia is almost entirely concerned with convergent squint. Likewise the main characteristics of convergent squint are amblyopia and poor fusion, fusion being the ability to get a single cerebral impression when objects fall on corresponding portions of the retina. These factors are only rarely present in divergent squint.

Amblyopia in squint is directly proportional to the age at which the squint occurs—the younger the individual the more rapid the loss and the more profound the amblyopia. Children who squint in the first or second year lose all vision in a month or two and children of six or seven years lose little or none. The cause of the amblyopia is a central scotoma or blind spot of approximately ten degrees corresponding in size to the papilo-macula bundle of the optic nerve. Toxic amblyopia, due to alcohol, tobacco, quinine, lack of vitamin B and multiple sclerosis have some of the same clinical characteristics as amblyopia of squint.

In addition to the central scotoma, contraction of the visual field is also present. Congenital amblyopia, or congenital failure of the central vision to develop, may occur with or without the presence of squint. Such cases, however, do not

*Read before the annual meeting of the Minnesota State Medical Association, Rochester, Minnesota, April 24, 1940.

show shrinking of the peripheral fields when not associated with squint. It is not to be inferred, however, that the congenital amblyopia is the cause of squint for in the majority of instances the amblyopia is not the cause but the result of the squint. In the two case histories which follow, both children had a definite congenital amblyopia, although squint never occurred in either case. Other factors beside amblyopia itself are necessary for the production of squint.

Case 1.—B. C., aged six, complained of no symptoms, but his parents were advised to have his eyes examined by his school teacher.

Examination revealed the following—Vision: Right, 20/20; Left 10/200. Retinoscopy: Right + 350S + 50 × 90 = 20/20; Left + 600S + 125 × 100 = 8/100. Muscle balance: There was no deviation either for distant or near vision. Treatment consisted of constant occlusion for nine months. There was no improvement in vision.

Case 2.—F. K., aged 7, was brought for examination because the family thought his eyes were weak. He had had smallpox and impetigo when ten days old and one eye was slightly red at that time. Vision: Right, 10/100; Left, 20/20. Muscle balance: Eyes showed no deviation on screen test and have never crossed. Retinoscopy: Right + 50S; Left + 25S + 25 × 90.

The cause of the central scotoma is entirely theoretical as no opportunity has ever been presented for microscopic study. Many feel that the amblyopia is dependent upon some defect in the optic nerve itself. Professor Tscherning expressed this belief to me personally some years ago and was of the belief that some anatomical change would be found if one were fortunate enough to secure such a specimen for microscopic examination. He believed, also, that the improvement in vision was entirely a matter of education. Others compare the loss of vision to the inability of deaf mutes to talk. If hearing is lost before four years of age the child will certainly be mute. If hearing is lost after four years and before seven, mutism will probably be present and if after seven years the child will talk even though he is not able to hear.

My personal feeling on the subject is that amblyopia is most often a functional disturbance or a mental adjustment of the individual in order to prevent diplopia. It is surprising that when the two eyes have equality of vision that alternating rather than monocular squint occurs and suppression of the image, or central scotoma is present only in the deviating eye. When the deviating eye fixes, the central scotoma disappears spontaneously. This type of central scotoma can also be demonstrated in individuals who are using a monocular microscope in which both eyes remain open but only one eye fixes, or in many individuals who use one eye for reading; consequently reading has a tendency to be more of a monocular than a binocular effort.

It is also important to remember that in alternating squint where one eye changes more rapidly than the other the squint may become monocular and amblyopia result. Then, too, the functional nature of amblyopia can definitely be demonstrated by the recovery of normal vision after occlusion of the fixing eye or by the complete loss of vision in an occluded eye which was previously normal. The following history represents such a case:

Case 3.—J. W. The eyes of this patient began to turn shortly after birth. On first examination at two years he had a 25 degree convergent squint in the right eye and a marked amblyopia. The left eye was immediately occluded and such occlusion was continued for one and one-half years. No examination had been made for one year, and when seen at this time the vision in the right eye was normal and the left eye practically nil. At four years of age, occlusion was changed to the right eye but it was never possible to improve the vision in the left eye, which had been occluded for a long period of time, without an examination. The vision in the right eye has remained normal and the vision in the left eye 4/200 and not improved. Surgical correction was necessary to correct the cosmetic defect.

Much speculation has occurred concerning the age at which vision may be recovered when the loss is due to amblyopia. It is generally considered that little vision is regained after the seventh year although there are many cases reported which indicate that such recovery may take place at a later age. It is important, however, to remember that some individuals do not have a definite scotoma but the vision is held in abeyance only because of a high refractive error which improves readily a few months after correction of the error has been made. When true amblyopia exists with a definite central scotoma, the vision which is regained after ten or eleven years of age is entirely inadequate for the individual to carry on many of the useful pursuits of life. Such is represented by the history given in Case 4.

Case 4.—M. M. developed convergent strabismus at three years and when first seen had a convergent strabismus of the right eye and a marked amblyopia. At eleven years of age she developed a choroidal tubercle in the left macula area with relapses in the next five years until the vision of the left eye became 20/200. Original vision of 20/200 in the right, or amblyopic eye, which had been used for the past nine years, has been checked at frequent intervals since that time and has never improved beyond 20/50, while the left eye remained at approximately 10/200 without central fixation due to the macular lesion.

There are far too many cases of amblyopia in every community and much of the fault rests entirely with the medical profession. Advising parents to wait until school age, when squint occurs at two or three years of age, is as false as postponing treatment in any acute disease. Such advice must, however, have arisen with the profession itself.

That amblyopia can be relieved in some, if not in all cases, is shown by the following case histories along with approved methods of treatment:

Case 5.—J. J. developed convergent strabismus at nineteen months and had had part time occlusion up to five years of age at which time the vision was: Right, 20/20; Left, 20/50. Total occlusion was, a this time, instituted and continued for six months when the vision became 20/20 in each eye. Orthoptic training was then instituted and a fair degree of fusion developed but with a deviation of approximately 15 degrees for distance and 30 degrees for near. Surgical correction should, at this time, have been instituted, yet, in spite of the deviation, the vision has remained normal for the last year and a half and should, at this time, be well established.

Case 6.—J. E. S. had had a convergent strabismus practically since birth with reduced vision in the left eye treated by occlusion and orthoptic training. Treatment was first instituted at three years, was continued for the next two years at which time the vision became normal in either eye with a deviation of approximately 15-20 degrees convergent strabismus and constant fixation of the right eye. At this time recession of the left internal rectus and resection of the left external rectus and continued orthoptic treatments produced binocular fixation and normal vision. It is doubtful if the fixation could have been maintained without surgical correction because of the marked contraction of the left external rectus.

There are several factors which should be stressed. Occlusion when used should be total. Part time occlusion is of little value. Frequent examinations to determine the vision of both eyes is imperative. When normal vision has been acquired, yet fixation does not occur spontaneously, such lack of fixation may be due to muscular contraction of the internal rectus. It requires more nervous energy to fix with a squinting than a non-squinting eye due to structural changes in the muscles. Consequently, surgical correction of the anatomical changes are necessary to help maintain fixation.

The operation of recession or retroplacement of a contracted muscle and subsequent resuturing of this muscle to the eyeball and the routine use of intratracheal general anesthesia have greatly improved operative results.

CONTRAINDICATIONS TO ESTROGEN THERAPY

Malignant growths of the mammary gland and the uterus have been induced in rodents with estrogens by numerous investigators. Some physicians, however, have doubted that the therapeutic administration of estrogens in the human being could result in the development of similar malignant growths. It has been pointed out that, theoretically, tremendous dosages of estrogens might be required to induce human cancer, when calculated according to body weight. No doubt estrogens have been used intensively for relatively too short a time to warrant the conclusion that mere absence of reports from the literature justified a disregard for the possible consequences of estrogenic therapy. Recently two significant reports have appeared which should indicate the possible dangers of administration of estrogens; one reports a case of mammary cancer following prolonged use of estrogens, and the other reports the appearance of carcinoma of the cervix in three patients among forty-three who were treated with estrogens for kraurosis vulvæ and senile vaginitis. The Council on Pharmacy and Chemistry and THE JOURNAL have repeatedly warned against the indiscriminate and prolonged use of estrogens and have emphasized the possible occurrence of mammary carcinoma in patients who are susceptible to the development of such malignant growths. It would be unwise to consider that there is safety in using small doses of estrogens, since it is quite possible that the same harm may be obtained through the use of small doses of estrogen if they are maintained over a long period. While there appears little or no evidence to indicate that normal women may develop such malignant growths, it would be well for the physician to realize that this is by no means an impossibility in patients who have a personal or familial history of genital or mammary cancer. It has been reported that the new synthetic estrogen diethylstilbestrol is far more active than the natural estrone and estradiol in the production of uterine and extra-uterine fibroids in guinea pigs. There is no evidence, however, that it is more carcinogenic than these substances. (Jour. A.M.A., April 20, 1940, p. 1560.)

THE COMMON BEHAVIOR PROBLEMS ENCOUNTERED IN THE PRE-SCHOOL PERIOD*

ERIC KENT CLARKE, M.D.

Professor of Pediatrics and Psychiatry
University of Minnesota Hospitals
Minneapolis, Minnesota

CHILD psychiatry is a recent development in the sphere of medical sciences. It came into being with the professed goal of attempting to prevent the high incidence of mental deviation encountered in the adult years. It is generally accepted that the onset of mental disease is seldom sudden, but is a gradual accumulation of maladjustment that can frequently be traced back into early childhood.

The problems of the pre-school age are important, for during these brief years the fundamental patterns of meeting life's situations are laid down. As our understanding of psychiatric problems broadens, this period acquires greater significance. If we are to be successful in the campaign of prevention of mental disorders, it cannot be overlooked.

Until recently, illness in children was regarded as part of general medicine. The same procedures that were followed with adults were considered appropriate in modified form for the child. It is a short half-century since the branch of pediatrics became a separate entity. Its early years were devoted to the evolution of scientific infant feeding, the management of the acute infections and the care of the chronically ill. Modern methods, the advances made in bacteriology, more accurate means of diagnosis and effective specific treatment aids have entirely altered the type of problem that confronts the pediatrist of today. There is now time for him to direct attention to the consideration of each patient as an individual and to evaluate his needs. The recent report of the American Board of Pediatrics, published in the *American Journal of Pediatrics* of February, 1940, outlines a course of study in child psychiatry the Board feels would be of practical benefit to pediatricians. This is concrete evidence of the recognition of the importance of emotional problems in the sick child.

Child psychiatry is a more recent development than pediatrics. In America, the first children's clinic was established in Chicago in 1909 by Dr. William Healy, the present director of the Judge Baker Guidance Center in Boston. From this early Chicago clinic great things have grown. Our guest speaker this afternoon, Dr. Paul Schroeder, the present director of the Institute for Juvenile Research, today carries on the work of the original clinic established by Dr. Healy. The credit for much of this development belongs to the Commonwealth Fund and the National Committee for Mental Hygiene, which so generously jointly sponsored the demonstration child guidance clinics. The Rockefeller Foundation also has given financial support to this activity. This type of service is past the experimental stage. From the single clinic in 1909 and the half dozen of 1920 there are today approximately 500 child guidance clinics spread across this country.

Until recently there was but a fragile bond of interest between the pediatrist and the psychiatrist interested in children. Each felt that the other's territory held little interest for him. Few understood the jargon of the other, as each attempted to separate the child into his physical and mental sections. The pediatrist recognized that the child had a mind, but thought it was of little importance in his treatment plan. Often a blank wall of resistance was raised by the pediatrist toward the psychiatrist. On several occasions in my early days in this work I was invited to speak at pediatrics meetings and found many of the pediatrists departed before I started. They felt that a psychiatrist was bound to confine his remarks solely to sex conflicts in infants and were not interested. Usually the same few friends stayed to listen because they had found, several of them through the medium of their own children, that perhaps some useful comments might be offered.

The reception at the psychiatric meetings was not much more cordial than that received from the pediatrists. Ten years ago, at the American Psychiatric Meeting in Toronto, I was invited to read a paper entitled "Psychiatry in the Pe-

*Presented before the annual meeting of the Minnesota State Medical Association, Rochester, Minnesota, April 24, 1940.

diatric Department of a General Hospital." This study was based on four years' work at the Strong Memorial Hospital at Rochester, New York, where Dr. McQuarrie, the present professor of pediatrics at the University of Minnesota, and myself both were on the staff and had worked in close coöperation on our common problems. The psychiatrists interested in child guidance at that Toronto meeting neatly dissected the paper, in which was made the premature statement that " the psychiatrist had temporarily assumed the sponsorship of work with children for the pediatrician with the aim of ultimately returning it to him." The attitude was that the two fields were and should be strictly delineated. I disagreed with the point of view, for it was felt that this was the weak spot in the development. I continued with my plan of coöperation and am pleased to see a gradual capitulation of both pediatrists and psychiatrists.

Our work at the Psychiatric Clinic for Children at the University Hospital and earlier in the clinic at the University of Rochester has indicated the necessity for a close bond between these two fields of children's work. It should be fully recognized that the psychiatrist has no desire to supplant the pediatrician, but strives to complement him. The latter, however, should be trained to be alert for the emotional components that occur in sick children. Once he has become aware of their presence he can plan a course of action toward their elimination. He will find that the majority, if recognized early and managed sympathetically, will disappear. This is the truly preventive work of mental hygiene.

Where the problem is already well established and the environmental factors so formidable that treatment procedure is complicated and time-consuming, it becomes impractical for the pediatrist to attempt to carry it out. Reference to the psychiatrist is then indicated. The special facilities of the child guidance clinic can be marshalled effectively to deal with complicated situations. Here each problem is approached from the angles of physical health, intellectual and emotional endowment and environment. In a high percentage of problems referred to us for study, not only in the pre-school group but also in older children, the difficulty originates with the adults who surround the child rather than with the child himself.

Those of pre-school age coming to the hospital psychiatric clinic present predominantly physical problems that have led to reference for study. The most common problems of this group center about feeding difficulties. Probably the clearest picture of them can be given by briefly presenting a few typical cases.

Case 1.—J. C., aged twenty months, was referred to hospital by the family physician with a history of regurgitation of ten months' duration and a tentative diagnosis of pyloric stenosis. Every approach had been tried by the family physician without success. Various modifications of diets had been attempted, and at the time of reference the child was on twelve hourly feedings per day. These she regurgitated regularly. When making the hospital arrangements over long-distance phone, the family physician outlined the history and added, "The parents are a pair of old maids. The father is as bad as the mother. They never should have had a child. They will run you ragged." Obviously the physician displayed a strong emotional reaction against them.

J. was a bright, well-nourished child in spite of her history of regurgitation. Complete physical study revealed no pathology except an exceptionally irritable gastro-intestinal tract that would indulge in active retro-peristalsis with minimal stimulation. J.'s most expressive remark was, "I'm going to be sick," after which she usually was.

J. was the only child of parents in their late forties. They had been engaged twelve years before marriage. The father, a prosperous village business man, had been dominated all his life by his mother, who disapproved of his contemplated marriage. He was neurotic and a patent medicine addict for many vague complaints. He felt guilty that his poor health was responsible for the misfortunes of his child. The mother, who throughout the long engagement had taught school, was an intelligent, but frustrated, woman. She had equal guilt fears that the long delay in pregnancy, coming near the menopause, was responsible for the difficulty. Both parents knew that this would be their only child. Consequently they were apprehensive over her survival. The mother had given her undivided attention since birth, and the preceding year during the child's illness had not left her for a moment. It was only fear in both parents that had induced them to bring her to the hospital. The mother sought admission for herself so that she could be near the child.

In the hospital the child was whiny and expected to be the center of attention. She was early placed on a regular diet suited to her needs. If she lost a meal, nothing was forthcoming until the next meal. At first she resented the other children as she had never been close to others before. Later she became interested. After ten days in the hospital she was brought into the nursery school group for play periods. Her first reaction was to demand every toy from other children, going from one to another. When refused her reac-

tion was, "Give it to me. I'm going to be sick." One three-year-old boy refused to give in and upon J.'s threat of illness called to the rest of the group to watch J. be sick. When requested thus to demonstrate, J.'s ability for once failed. This incident marked the beginning of a new era of constructive education. Contact with children accomplished what adults had failed to do. The regurgitation had no more serious basis than a pair of over-solicitous parents and a poorly directed medical program that ignored emotional tension in both parents and child. Our treatment capitalized the reassurance of the parents, the removal of many of their frustrations, demonstrating to them that their child could be a normal youngster. The outcome was good as the parents both developed understanding and outside interests that gave them other things to think about.

Case 2. A second variety of feeding disturbance is represented by R. L., a three-year-old daughter of a physician. The mother before marriage had been a graduate nurse. R. from an early age had many allergic reactions such as to milk, wheat flour and many of the common foodstuffs. In addition, infections increased her anaphylaxis. She twice had pneumonia in addition to double mastoidectomy. She was frail, underweight and high strung, and being intelligent had learned to dominate the family by refusal to eat. Both parents were aware of the narrow margin of safety and became unduly apprehensive when she refused food. Mealtime became a daily battleground of coaxing, wheedling, and promising. The parents realized their approach was wrong, but admitted that she had them beaten. They asked that she be admitted for study and training. R. was an old friend in hospital, where she had often been during serious illnesses. This time she was ambulatory and after preliminary study came to nursery school each day from the hospital ward. The first meal she was placed with other children, under the existing rule that none could leave the table till all had finished. R. toyed with her food while the others waited. The span of patience of three-year-olds is short. Restlessness grew intense. Finally a boy said, "Tomorrow you put R. at another table. We don't want her with us. She is too slow and spoils our fun. We want time to play." This was her first encounter with disapproval. Coming from a contemporary it carried weight. The next day no one wanted her at their table because of her slowness. She made some effort to coöperate and finished a small serving in acceptable time. Each day her plate was filled a little fuller until she was consuming an adequate amount. For weeks after discharge to her home from the hospital she got along on one full meal a day. She would eat heartily in nursery school, but usually refused breakfast and supper. As the parents acquired reassurance, they began to ignore her and made little effort to persuade her to eat. On one occasion they suggested that as R. probably could not eat all her portion, she might share it with her brother. R. left none to be shared. As casualness and a sense of security grew in the parents, R.'s efforts to dominate decreased. It was encouraging that with the diminution of tension there was an accompanying lowering of allergic response.

Feeding problems frequently originate after serious illness, but persist long after the convalescence has ended. The mechanism of production is easy to understand, but the reason for perpetuation is not always so apparent. The explanation can usually be found in parental attitude toward food. Over-emphasis defeats the purpose if the child learns he can gain attention by refusal to eat.

The elimination of a feeding problem is important. It may be the starting point of a gastrointestinal neurosis, so common in adult years, that has progressively passed through the stages of food fads and idiosyncrasies to more exaggerated manifestations.

Once the physician has completely ruled out the possibility of an organic basis for refusal of food the task is only partially complete. The reeducation of parental attitudes is equally important. The frequency with which these children reach the clinic indicates that the correction of a feeding problem is not always easy. Reeducation is often time-consuming. Occasionally it becomes a formidable task, involving the reorganization of many fundamental principles in the lives of both parents that exert unfavorable influence on the offspring. It is time well spent, for the persistence of these traits will produce undesirable reactions in different forms at a later date.

Temper tantrums and fears rank second and third in order of incidence of referral to the clinic. We suspect that in actual occurrence these are more frequent than the feeding problems. They do not reach the clinic because they do not represent a comparable threat to survival. The parent expects that it is a transitory inconvenient phase that will be outgrown. Like the feeding problems, the persistence of these reactions should be cause for concern, for when they are perpetuated into the adolescent and adult life, they often become major handicaps to success. Again it is essential that the physical status of the child be thoroughly investigated. In the absence of pathology, attention should be directed toward an investigation of the system of management. It is easy for these patterns to become established in a child below normal physically.

The threshold of fatigue and sensitivity is lowered, tension is increased, impressibility is heightened and misbehavior results.

In a child who is well the incidence of tantrums and fear become symptoms of ineffectual management. The busy practitioner is prone to consider the treatment of tantrums and fears beneath his dignity, beyond the superficial suggestions of isolation and ignoring the tantrum or reassurance in the case of fear. The true explanation often lies much deeper and must be considered if sound foundation for satisfactory future development is to be laid. Malignant parental attitudes toward the child may first attract attention through outbursts of temper in the child. Parental rejection may influence the system of training, against which, as a result of frustration, the child expresses himself explosively. Careful analysis of the situation that eliminates the source of friction may prevent more serious developments at a later period. Veiled antagonism by a parent toward his child may produce many other types of reaction besides tantrums and fears. We have seen many children whose response was: (1) wilful destructiveness; (2) aggression toward other children; (3) neurotic punishing reactions such as thumb sucking, facial tics and habit spasms, reversion to enuresis and soiling after satisfactory toilet habits have been established; (4) refusal to talk or reversion to baby talk. Reactions of this type may exist as single entities or in multiples. Little success can be expected from treatment if the emphasis is directed solely toward the child. Correction of the faulty parental attitude toward the child is essential if any permanent change is to be expected.

A typical response is demonstrated in the following case:

Mary L., four and a half years old, an only child, was referred for study by the family physician because of poor muscular coördination, lethargy, and flabbiness of muscles. The local doctor could find no evidence of organic disease but feared the onset of a progressive muscular dystrophy. Careful physical study revealed no definite reason for the condition although coördination was poor, she frequently tumbled, and all her movements were clumsy. Birth and health history were essentially normal.

The family background was important in that the parents had separated soon after Mary's birth. The father was an intelligent, but thoroughly impractical individual, with little sense of responsibility. After the separation he had drifted out of the picture. He made one feeble effort at reconciliation, which the maternal grandmother violently opposed. The mother had returned to live with the maternal grandmother. The latter had violently opposed the marriage and had grim satisfaction that it had not been successful, a matter in which she played no small part. The mother had not wanted the pregnancy, feared it throughout its duration and fear of further pregnancy featured in the separation. There was bitter resentment toward her husband, which carried over unconsciously to his child. This was camouflaged in seemingly genuine, conventional protest of anxiety. Mary strongly resembled the father in appearance. She was a rather plain child. The mother had pictured her daughter as a story book, doll-like creature. Mary's lethargy and clumsiness were further sources of irritation. The grandmother was convinced the child was feebleminded and constantly reiterated her opinion to the mother. The result was that the child was emotionally starved, and although given excellent physical care, was generally ignored. Long hours in a play pen without adequate opportunity for exercise or the stimulation of companions had removed all incentive toward activity. She was content to sit for long periods and look at pictures in books. She seldom talked or cried.

Mary was a pathetic youngster, who stood all the physical examinations stoically and impassively. She seemed entirely detached. On psychological examination she showed superior ability. The test was uneven because of her passivity. After physical study had revealed no basis for anxiety over her physical condition, she was seen regularly in the clinic. After considerable stimulation a brief spark of spontaneity could be aroused. It appeared as if she feared to enjoy herself. On one occasion in the playroom she made a feeble imitation of another child throwing a ball. It unfortunately hit a window, and although nothing happened, she could not be induced to touch another toy. The unhealthy emotional attitude that surrounds this child is largely responsible for the lack of development. Treatment has not been successful, for it has meant fighting the malign influence of the grandmother at each step. She does not want the child to be normal. The mother has been in a difficult situation because she does not dare defy the grandmother. Salvage was attempted by means of nursery school and a short period at camp. Attendance at nursery school was irregular, as the mother was willing to resort to any subterfuge to keep the child home. The period at camp was not long enough to accomplish much although Mary learned to dress herself. She took part in the games and seemed happy although aloof from the group. The grandmother is still convinced the child is subnormal. The mother retains her ambivalence and Mary continues to develop slowly. The tragedy is that there is nothing anyone can do to alter the situation.

The aim of the pediatrist should be directed not only toward the development of physically healthy children, but also toward the development

of mentally sound and well-adjusted individuals capable of functioning at the full level of capacity. It is his responsibility to see that the first steps toward emancipation from the home are taken early. These are often delayed until the child reaches school age. The poor preparation for group activity which is inevitable at this time may easily give rise to feelings of inferiority that impair good social contacts. Stress should be placed on the early acquisition of self-reliance and independence, for these are necessary attributes to a well-adjusted personality. Handicapping parental attitudes toward the child should be recognized and altered before they can wreak devastation.

As refinements of diagnosis and treatment methods have been developed in the realm of physical illness, the physician should have more urge to devote time to the study of the individual child as a human being in relation to his surroundings. If we are to advance in our program of prevention against mental illness, the start must be an active one during the pre-school years. Pediatricians and family physicians must feel more responsibility in assuming a broader understanding that emotional health is as important as physical health. To ensure good mental health the investigation must go more deeply than the consideration of the child alone, but often must extend to the reconstruction of attitudes of those who surround him.

When firmly established problems are encountered where the ramifications are so widespread that reconstruction becomes too time-consuming, the psychiatrist and the guidance clinic are prepared to assume re-education for the physician in practice. In this way the one branch of medicine supplements the other. If better mutual understanding of both fields is created, a much sounder and more productive order of prevention of mental illness, which today exacts such a tremendous toll from society, will result.

MENTAL HYGIENE IN THE SCHOOL*

ALAN CHALLMAN, M.D.

Director, Child Study Department
Minneapolis Public Schools
Minneapolis, Minnesota

THE public school offers an exceptional opportunity for public health work. While the physical health program with its required medical examinations and inspections, Mantoux testing and health education is better known and better developed at the present time than the program for securing better mental health among the pupils, it cannot hope to contribute as much to human welfare. In this paper I intend to present those major objectives of mental hygiene which are related to the school life of the child. These objectives may not seem very new or very dramatic; but they are sound and have been proved empirically in clinical psychiatric practice a thousand times over.

It is very difficult to say anything new about human nature. One of the great assets of mental activity is its ability to guess at things and often guess correctly. People have guessed and guessed about human nature, and have hit upon almost every possible theory to explain behavior. The undramatic task of scientific psychiatry is to discover what is true, and it is usually found that somebody's lucky guess has anticipated its results. The biggest contribution of psychiatric investigation is not in the novelty of its findings, but that it offers a safer basis for human progress than the flashy guessing of the amateur who, in the words of Artemas Ward, "knows so much that ain't so." It is usually "the stuff that ain't so" that makes newspaper headlines as scientific material about human nature today. It is sufficiently absurd not to disturb anyone's psychological defenses. Valid observations are usually "old stuff" if they are not offensive—which is to say, if they do not attack our defenses against our repressions.

If a scientific observation of psychiatry does attack our psychological defenses, it is usually counter-attacked by a motley group rang-

*Presented before the annual meeting of the Minnesota State Medical Association, Rochester, Minnesota, April 24, 1940.

ing from the most poorly educated charwomen to the most successful and best publicized scientists who can be scientific about everything but their own private lives. This paper, let me hasten to assure you, should not attack your defenses. But to get into our subject—

Mental health has been defined by the White House Conference as "the adjustment of individuals to themselves and the world-at-large with a maximum of effectiveness, satisfaction, cheerfulness, and socially considerate behavior, and the ability to face and accept the realities." Defined in another and more negative way, mental health work seeks to reduce the occurrence of mental disease, personality handicaps, feeblemindedness and delinquency. All of these latter conditions represent failures in the adjustment of the individual to life, and constitute a major problem in our civilization.

Each year there are as many first admissions to mental hospitals as there are students matriculating in our Universities. Five per cent of all fifteen-year-old children will develop such a serious mental illness sometime during their lives that they will be forced to enter a mental hospital. In addition to these severely maladjusted people who occupy more than half of all hospital beds, there is a much greater number whose lives are detrimentally affected to a lesser degree by minor mental illness such as neurosis, or by personality handicaps such as inferiority feelings, self-consciousness, moodiness, sensitivity, irritability and the like. This latter group may be likened to sufferers from arthritis whose efficiency and happiness in living is materially reduced, although they are not denied the appearance of normal health.

A mental hygiene program in a school system works to reduce the number and severity of these handicaps as they develop in school children, and furthermore attempts to bring about a situation in schools that will promote better mental health in all pupils. At the present time, this goal is sought through the discovery, and elimination or reduction, in the obstacles to mental health that arise within the school system itself. Quite a number of these obstacles that warp children's personalities and tend toward the production of maladjustment, mental illness or delinquency have been discovered, and constant progress is being made in their removal.

School Failure Forced Upon the Dull

What are some of these obstacles or sources of infection, as they might be called by analogy? The first and perhaps the best recognized factor that attacks mental health in the school is the impossibility for the duller children to win success, no matter how hard they try. There are perhaps ten to fifteen per cent of the school population who are innately lacking in intelligence or school ability to such a degree that they are denied the opportunity to do a satisfactory job. This, of course, produces frustration and a feeling of inadequacy which is unhealthy. Nature's defenses begin to work then in these children, and compensations are sought for this need which is unfulfilled. Some children may be fortunate enough to have assets in physique or special abilities, etc., so that they can compensate in a way which is not harmful. Others, however, possessed of no such equipment, may find compensation in retaliatory, bad-boy behavior or through withdrawal into phantasies of success and the like, and the basis for further maladjustment or mental illness is laid.

Child Guidance Clinics can show case after case of personality maladjustment that went to extreme degrees with this factor of the impossibility of winning success and approval in academic work as the sole or coöperating etiological agent. This particular obstacle to mental health arises out of the fact that it takes a full six-year mental age to handle first grade work, a seven-year mental age to handle second grade work, etc. A child with an I.Q. of 80 for example, is not mentally up to the average six-year-old until *he* is eight years old. He simply can't do first grade work in a satisfactory way until he has spent two years more in developing his ability than the average child takes to reach that point. If he enters school when he is six, failure is forced upon him in spite of his best efforts to keep up with his age group. In the past, he has either been held back and forced to repeat the grade, or sent on to the next higher grade where he found daily failure in his assigned tasks facing him again.

The only way that this obstacle to mental health may be reduced is to teach the child in school what he is able to learn—no more and no less. It is perfectly possible for teachers to know in the present day what school ability a child pos-

sesses. The individual intelligence tests have proved themselves to be beyond doubt a very reliable measure of academic ability. School administrators and boards can make these measurements available to teachers on all pupils so that, knowing what the child is capable of learning and what he is not capable of learning, the teacher can adjust her teaching to his level of ability and avoid the mentally unhealthy result of requiring work that can't be done. This, of course, means that the teacher must individualize her work in the classroom, and that can't be done unless the size of the class is smaller than when the group is treated as though it is homogeneous in the matter of school ability. This adjustment to the needs and capacities of the individual children is being made in an increasingly large measure throughout the country, and it is largely due to the mental hygiene emphasis upon this point as a fundamental necessity in securing better mental health for pupils.

Poor Work Habits Resulting From Brightness

A second factor in the school producing maladjustment and personality distortion is closely related to the first. It is the lack of challenge and interest that results when a child much brighter than the average is given tasks too easy for him. Habits of indolence and lethargy and a feeling of false superiority may be produced which handicap the child throughout the rest of his life. Good work habits are of tremendous importance in determining a person's success in later life, and frustration and failure in meeting expectations are often the lot of the adults who were allowed to "get by" too easily in their school years because of superior intelligence. The remedy that is recommended and is being put into application slowly in schools to correct this obstacle to mental health is the same as in the case of the adjustment to duller children. In this case, of course, the pupil being *more* capable is given work of a more difficult grade—work that is challenging and interesting.

Effects of Specific Reading Disabilities

A third obstacle to mental health found in our schools arises out of the fact that reading and writing are such important tool subjects that everything else depends on the ability to master them. Now some children, though otherwise intelligent, suffer from a specific disability in learning to use written language. We all recognize readily that an intelligent person may be tone deaf and find it impossible to recognize or sing a tune correctly. That represents a specific disability in music. People so handicapped are not bothered much by it because it is possible to avoid singing without dire consequences. Not so in the case of those individuals who can't learn to read or spell with ordinary proficiency, however. Such cases were first described by Kussmaul in 1877, and he called them "word blindness." Hinshelwood, a English ophthalmologist, gave us the first intensive study of the condition in a monograph published in 1917. Many children had been referred to him because it was thought that their inability to read was due to some disorder in vision. This did not prove to be the case, but Hinshelwood called attention to the fact that there were often several such cases in one family, and that the symptoms these children showed were closely parallel to those which appear in some adults who have lost the capacity to read through an injury to the brain. He thought the condition might be due to an agenesis in the angular gyrus (speech area) of the dominant hemisphere. Evidence from autopsies has not supported this theory. Samuel Orton at New York Neurological Institute has done a great deal of work with this condition, and has named it strephosymbolia, meaning "twisted symbols." One of the prominent diagnostic features of these cases is that they make many reversals and inversions of letters and syllables in reading and writing. "Dog" is read "God" and "on" is read "no," but such errors are not made consistently by the child so that a word may be read correctly once and reversed the next time it is met a line or two down the page. The letters *b, d, p* and *q* are usually very badly confused due to their similarity. These children may be so severely handicapped that they are still unable to learn to read even the simplest material after years of schooling. One eleven-year-old boy with superior intelligence whom I saw could not read a single word, and could recognize only a few of the letters of the alphabet. Others are not so severely handicapped, and may be able to read and write with great difficulty and always make a large number of errors. About two per cent of our school children are so seriously affected by specific reading disabilities that they can make only the most

meager progress in school work. The disability seems to be related in many cases to speech defects and to shifts in handedness from one side to the other.

The personalities of these children usually become seriously distorted because they are so often taken to be feebleminded. They even seriously question their own intelligence. If their intelligence is recognized, they are then thought to be stubborn by their teachers and parents, and under the pressure that is put on them to learn to read often grow to justify the characterization. All forms of compensatory behavior show up in these children. Their relationships to their teachers, companions, and even parents is oftentimes deleteriously affected by their school failure and very undesirable personalities may result.

From the standpoint of school mental hygiene, an adjustment must be made to these children. Fortunately, it is possible to teach most of these children to read and spell satisfactorily if they can be given individual instruction by a patient, kind person who will try out all the techniques that can be used to teach reading until she finds out what will work for this particular child. The more progressive school systems are employing such tutors and also training some of the teachers in lower grades to use a wider variety of teaching techniques while avoiding a degree of pressure that develops an antipathy to the subject in the pupil.

Teachers' Personalities

A fourth obstacle to mental health in the school is often found in the personality of the teacher. Several careful studies have shown the greater percentage of personality and behavior problems that appear in the classrooms of embittered, harsh, cold, perfectionistic, sadistic or pedantic teachers. Parents who are good observers can usually notice the changes that show up in their own children's personalities as they move along from one teacher's influence to another. Teachers who, out of some personality quirk of their own, require the pupils to maintain a "pin-drop discipline" and to behave in such utterly unchildlike ways—ways which are inappropriate to any other contemporary or future situation—do a considerable amount of harm to children's personalities and should not be allowed to go on with their methods.

One should not be too harsh, however, in condemning the teachers for unfortunate personalities, because the narrow way in which they are required to live by the parents and community as a whole is so unrealistic and unhygienic that it, in effect, forces them to develop unhealthy qualities. The sanctimonious behavior that is required of them, the deprivation of the right to marry and still hold their jobs, the inadequate salaries many of them have to exist on, all foster suppression and frustration and personality distortion. Such regulations and super-moralistic requirements made upon school teachers tend to keep out of the profession many normal, warm, vital personalities and tend to produce maladjustment in those who remain in the work. This has its undesirable consequences in the pupils' personality development.

A thoroughgoing effort to solve this problem of securing teachers with normal personalities and keeping them that way can hardly be said to exist any place in the country today. Teachers are still being selected very much in terms of their academic records alone with no consideration given to the effect their personalities will have on the pupils' mental health

In closing, I should like to impress upon you again that these problems of which I speak are *health* problems. They have had all too scant attention from physicians who are otherwise interested in promotion of health and disease prevention. There is nothing vague or abstract about these obstacles to mental health. It may be that the average physician's dislike for personality problems, which probably arises out of his feeling of unfamiliarity in this province of medicine, has prevented him from finding the causes for the behavior disturbances he sees in his practice. Work such as is being done in the child guidance and other psychiatric clinics throughout the country is clearing up a good many of the mysteries of personality distortion and bringing order into a field which at one time was completely chaotic. The obstacles described briefly in this paper are matters about which there is general agreement among child psychiatrists and progressive educators. How many of them are still operating in your community to cut down the chance for mental health of the young people growing up there? How long will it be before the physician recognizes his responsibility to contribute to the elimination of these health hazards in our schools?

EMOTIONAL FACTORS IN ORGANIC DISEASE*

PAUL L. SCHROEDER, M.D.

Director, Institute for Juvenile Research
Chicago, Illinois

THE doctor's first interest has been the cure of the sick. He has been most concerned with those critically ill. Because of this, his patients have been those who suffered with the more grossly pathological conditions and who therefore deviate most from the normal. The modern doctor is also interested in the prevention of disease. As his understanding of the well person has grown, he has become increasingly more concerned with preventive medicine.

This is the experience of the doctor in the diagnosis and treatment of organic diseases. In the treatment of functional diseases much the same progression has occurred. At first only the obviously insane were considered the province of the physician. As his knowledge of those with grossly abnormal behavior grew, he found that often the underlying causes of these diseases were found to have their beginning in childhood. Accordingly in time the physician extended his practice to the treatment of the less seriously mentally ill to include as well children with emotional disturbances.

Although the physician in the past has been concerned with the psychic disturbances which occur in the presence of organic disease, he has relegated them to comparative unimportance. In his study of the patient, he drew a definite line separating the mental and the physical findings. Failing to find evidence of organic disturbance, he dismissed the patient with the statement that his symptoms were a figment of his imagination. Having made such a diagnosis, his interest and concern ceased. However, the concern over the patient continued in another sphere, a sphere which, though largely legalistic, was actually the concern of the social worker. It was represented in the asylums for the insane.

The first real understanding of the illnesses of these patients followed the sociological contribution of Clifford Beers in his own story, "A Mind that Found Itself." This is the story of his experiences as a patient in the general hospital, later the private hospital for the mentally ill, and finally the state hospital for the insane and contains his recommendations for reform in the cure of the mentally ill. His indefatigable efforts in behalf of the mentally ill changed the point of view of the physician as well as the administrator. It was about this same time that Sigmund Freud made his early contribution to the understanding of the psyche.

From still another field there was evidence of the shift from the desire for vengeance to control of crime through a therapeutic device. This was represented in the program of probation and parole, the first of which went into effect nearly one hundred years ago.

About this same time, there were evidences in other fields of a changing attitude toward the misconduct of persons who presumably were without organic disease. I refer to the change from the determinate to the indeterminate sentence for the adult criminal. Such changes suggest that the community has come to be more interested in the offender than in the offense.

From still another direction came an approach to the problem in behalf of delinquent and criminal children. It was in 1899 in Chicago that the first Juvenile Court was established. The so-called sentimentalists' point of view held that delinquency and criminality in children were symptomatic rather than inherent and that the conditions which were reacted to with delinquency were remediable. In its philosophy there was the principle that punishment to be effective must be administered as treatment directed towards the correction of the causes underlying delinquency.

We may consider, then, five separate efforts for the better understanding of conduct disorders in human beings, the first of these being a continuation of the progress of scientific medicine; the second, the combined efforts of medicine and sociology in behalf of the insane; the third, the practice of probation and parole of criminal offenders; the fourth, the institution of the principle of indeterminate sentences; and the fifth, the Juvenile Court, and behavior clinic with its combined medical, psychological and sociological ap-

*Read before the annual meeting of the Minnesota State Medical Association, Rochester, Minnesota, April 24, 1940.

proach to the understanding of behavior difficulties in children.

Although a generation ago, scientific medicine did not concern itself with the gross disorders of conduct, the last twenty years of medicine have brought a great change in this direction. However, in spite of this, the physician still rejects as a problem of some other worker, the person whose symptoms cannot be explained as of organic basis. A significant change in this attitude is expressed by Barrow in his lectures published under the title, "The Patient and the Art of Living—An Approach to Psychosomatic Medicine."[1] Barrow has given to the student of medicine his approach to the patient and defines psychosomatic disease as follows:

"A condition in which the chief complaint is usually physical, the subjective symptoms are usually out of all proportion to the physical findings, and there is always an underlying and often obscure mental or psychic disorder based on a constitutional inadequacy and on some environmental or circumstantial conflict."[1]

To illustrate the importance of dealing with the patient's problems as a whole, he quotes from the record of a patient examined by a psychiatrist.

"The patient had been told that she was a Peter Pan type of individual, that she would have been all right if she could have remained a child and that it was a mistake for her to have assumed the strain and obligations of married life and motherhood. 'Well,' she said, 'That may be true, but what am I going to do about it now? I still have headaches.' "[1]

Dr. Barrow adds:

"I do not wish to minimize the help that may be rendered by psychiatric consultation and advice but what is needed in the attending physician is not a highly specialized knowledge of psychiatry or of any other of the specialties but rather a breadth of medical vision and skill that will enable him to make the patient comfortable. In addition he must have a large fund of patience and compassion and common sense so that he can establish contact with the patient and win his confidence. The proper approach to these cases might, therefore, be said to be one-third psychiatric, one-third physical and one-third compassionate guidance in the Art of Living."[1]

Barrow reports the findings in a series of 250 patients whom he classified as psychoneurotic persons. In his series, 37 per cent complained primarily of gastro-intestinal disturbances. Second in frequency are cardiovascular symptoms, this being the primary complaint in 17 per cent. Then follows malaise and fatigability 14 per cent; aches and pains, 10 per cent; menopausal symptoms, 7 per cent; sore and aching throat, 5 per cent; arthritis, 4 per cent; genito-urinary, 3 per cent. He also includes neurogenic fever, a low grade fever for which no organic cause is determined. He suggests that in spite of the anxiety of the physician, the desire "to follow the daily temperature curve as a stock broker might follow the ticker tape, it is usually advisable to have the patient throw away his thermometer and forget his fever."[1]

In discussing anxiety states and depressive neuroses which account for about 40 per cent of the male cases, Barrow states that without psychiatric study it is seldom possible to find a cause.

"The anxiety state may often be traced to childhood environment or experiences, even to anxieties never consciously experienced; but the emotional state has been 'displaced' from the original object and transferred to other objects, or anxiety has in fact become a habit of thought. Thus, for example, the child whose tranquillity and security have been threatened by marital discord of the parents grows up into a person surrounded with thick banks of gloom who, although he recognizes that he is no longer dependent on his parents for happiness and security, still approaches each new episode of life with fear. To treat these individuals properly, one must completely rebuild the personality, a task calling for a skilful psychiatrist."[1]

That considerable medical confusion exists over the significance of emotional factors even in the presence of organic disease is in part due to the looseness with which the term psychoneuroses is used, according to Esther Loring Richards.[4] She suggests that there is even some danger in affixing a label to such patients, even though it be a correct one. She writes:

"The term psychoneuroses sounds more modern and scientific than neurasthenia, but from the standpoint of usage and subsequent treatment of the patient it is equally dangerous. First of all, it continues to carry on the medical confusion of a sharp contrast between poor mental health that is supposed to be benign and poor mental health of the outspoken psychoses that are medically recognized as serious enough to call for instant psychiatric help. Secondly, the internist is encouraged by this same old concept to employ essentially one line of treatment for all people whom he considers psychoneurotic."[4]

This danger is also dealt with by Plant in his book "Personality and the Cultural Pattern." He refers to the tendency on the part of physicians to place human beings into certain categories based on an examination which does not include adequate consideration of the cultural background. For example, a patient who is said to be suffering from dementia precox and therefore incurable, acquires thereby an irrevocable future. It is a well known fact that whereas the admissions to the hospitals for the mentally ill reveal an incidence of about 30 per cent of dementia precox, the resident population is nearer two-thirds. In like manner, the child whose intelligence has been tested by a formal method thereby is "given an intelligence quotient" and is to some extent permanently categorized. Until we deal with the meaning that underlies our diagnostic findings, we shall not be able to avoid such dangers.

More recently there has been a growing tendency in the medical schools to teach that the diagnostic procedure must concern itself with the person as a whole and as a part of a larger presence extending into his immediate environment. This is perhaps an extension of the point of view of medical schools generally to teach not only the diagnosis of disease of the various organs but also the reasons for the treatment to be used, a change from the empiricisms of the past. Now we teach the student of medicine that he is treating the person who is sick rather than the disease from which he suffers. In so doing, we are concerned beyond the immediate presence of that person. We may look on our laws regarding quarantine as evidence of this point of view, though of a limited sort. In the course of a newer point of view, larger emphasis is given to the behavior of persons who are ill.

Tremendous and growing interest has been exhibited in the relationship between emotional factors and physical change. Flanders Dunbar has called special attention to these changes in her volume entitled "Emotions and Body Changes." Winfred Overholser, speaking on the rôle of psychiatry in general medicine bears this out in his statement:

"There has been of recent years . . . a tendency of the general practitioner and of the specialist to overlook the whole patient while being preoccupied with certain of his specific parts. Many common examples of the physical manifestation of emotional changes will readily come to your mind. I need refer for example only to the very uncomfortable symptom of blushing on occasions of embarrassment, the presence of goose-flesh and nervous diarrhea in cases of fright, and the various types of physical response to sex stimulation to indicate that it is a common experience and a matter of general knowledge that emotional factors can produce bodily changes. Yet how often this fact is forgotten when a patient comes to the surgeon complaining of enlargement of the thyroid! Investigation has shown that many cases in which the thyroid is evidently putting out an increased amount of secretion are primarily due to emotional conflict and respond promptly to the resolution of those conflicts."[3]

In addition to the growing realization of the significance of emotional factors as the underlying cause of organic conditions such as gastric ulcer and other gastro-intestinal disturbances studies have been made which indicate that essential hypertension and bronchial asthma have large psychic elements in their etiology. French reminds us:

"Since earliest times it has been suspected that psychological factors play some rôle in connection with bronchial asthma. In the last few decades the discovery of the significance of allergic factors in this disease has tended to divert interest away from earlier observations that asthma is frequently associated with some sort of emotional instability and that asthma attacks are often precipitated by acute emotional conflicts."[2]

He reports the results of the psychoanalytic study of twenty-four cases of bronchial asthma. He concludes:

"The asthma attack is precipitated as a rule by a temptation which threatens to estrange the patient from a mother figure. . . . Numerous possible defenses against this conflict would suggest that the common feature in the otherwise divergent personalities of our asthma patients is the fact that the personality of these patients is built up in large part around the task of mastering by one means or another the patient's fear of being separated from the mother. . . . All these observations would suggest that psychological and allergic factors probably stand in a somewhat complementary relationship to each other in the etiology of bronchial asthma, that in some cases asthma attacks may be precipitated by allergic factors alone, in others by emotional factors alone and that in still other cases cooperation of allergic and emotional factors may be necessary to produce the attacks."[2]

To illustrate what asthma may mean to the patient is the following statement:

"There seems also be a very intimate relationship between asthma and crying or laughing. There is

much to suggest in fact that the asthma attack is really a sort of equivalent of a cry of anxiety or rage which has been inhibited or repressed. One of the first reactions of the child upon separation from the mother at birth is to cry and during early infancy and even later, crying remains the predominant reaction of the child in situations of helplessness when he can only wish for the mother to return to him. In later life this primitive cry is modified into speech and in confession retains the function of maintaining the bond between the child and mother. For some reason, in the situations which provoke asthma attacks the child is unable to cry. . . . Of particular interest, however, is the fact that we are sometimes able to observe the cessation of an asthma attack and the appearance of crying in its place."[2]

Perhaps the best illustration of the emotional factors in the presence of organic disease occurs in persons who are left with an obvious physical handicap. Alfred Adler has shown rather clearly the tendency of the human to react to physical limitations in a variety of ways. His theory of the inferiority complex based originally on the emotional conflicts over the presence of a real handicap was later extended in its hypothesis to the reaction to a feeling of inadequacy and inferiority. This has been carried further, calling attention to the fact that inferiority may be only as the condition deviates from the accepted standard. For example, persons with red hair being in the very limited minority deviate from the standard for human beings as a whole. Lipemial persons with blemishes or those having a large nose or even a snub nose appear in a similar category.

William Healy early recognized the extraordinary behavior of children suffering with organic disease. In one of his early reports he describes a child who was brought to the Juvenile Court because of delinquency. This occurred after he had been frightened by confinement in the local police station without avail. This responsible and reliable family was deeply concerned over his stealing and his rather sudden school failure and were greatly disturbed over the necessity for court action. Examination made by Dr. Healy revealed that the child was suffering from juvenile general paralysis of the insane and that his sudden change in personality from an industrious, well behaved, promising school child to one of school failure, truancy and delinquency was a part of the change due to the presence of syphilis. In like manner, behavior difficulties have occurred in children with disabilities of a more obvious nature, but which lend themselves to therapeutic effort. For example, a child brought to us for examination at the request of the judge of the Juvenile Court had been charged by the police with twenty-five burglaries, all of which he admitted. His picture appeared in the newspapers wearing a man's felt hat, a handkerchief tied around his neck and a police revolver in each hand, with the caption "The Baby Bandit of Chicago." He was small in stature, came from a home in which the father was a rather poor provider but honest and reliable. The community in which he lived was classified as one of the middle class residential sections. The patient, though truant from home, had attended classes regularly. The school reported that he was a good student, an excellent reader, and in the fifth grade. There was only one complaint against him and that was that he was sometimes tardy in returning to class after recess. To the parents, his conduct was unbelievable. Examination showed that the patient was well nourished, well developed, with the exception of hypospadias. In response to intelligence tests he was found to be average and therefore properly placed in school. An attempt was made to get him to explain his conduct. To this he replied, "I can't make good. You've got to be a sissy to make good." A number of questions were naturally raised, especially with this comment from a boy who not only was obviously not a sissy but who admitted more criminal acts than he was guilty of. His father stated that until the child was about seven years old, he sat down to urninate. What happened after that time, the father did not know since the child would never permit a second person in the bathroom with him. We did have, however, in this an explanation for his tardiness at recess. Because of the presence of the hypospadias, he identified himself in a rôle which was intolerable to him. His violent reaction to it can be understood as the degree to which he rejected that rôle.

In planning treatment for this child, it became evident that some immediate steps must be taken to effect a change in his attitude toward himself and perhaps this would necessitate removal from the community. Possibility of plastic surgery was considered, but the recommendations were not carried out. Within three months, he was back in the hands of the police, having returned to his former behavior. This

time, the recommendations were ordered by the court to be carried out. In considering the usual indications for surgical intervention in hypospadias, one must consider here also the nature of the interpersonal relationships about to be thrust upon him by virtue of his emerging adolescence.

Let us pass to the consideration of emotional problems in children who are free from organic disease. By way of illustration, I should like to present the following case:

A boy fifteen years of age, living in a middle class residential section of a large city, was arrested by the police for stealing small articles from a department store, including mechanical pencils, rubber balls, and an inexpensive electric clock. Along with two other boys, he was also charged with damaging a number of women's hats as he poured liquid ammonia down an air chute in a store. In still another store, these boys threw stench bombs, one of them setting fire to drapes hanging over a railing.

When the police apprehended them, this boy accepted the major blame. He was placed in the Detention Home pending completion of the investigation.

It was rather surprising that this boy should become delinquent. He was doing excellent work as a sophomore in high school. He is the son of parents, both of whom are physicians, who themselves have strong moral convictions and who served as medical missionaries in China until the older brothers and sisters were ready for higher education.

The father is now president of the Parent-Teacher Association of the school which his children attend. In this family there are three older children in college; a younger sister is in high school. The burden of supporting these children is almost more than the father can afford, even though he has a busy practice of medicine among the people living in his community. Because of these limitations of funds and the rather positive convictions of the parents, the children are set apart somewhat from others. Their status in the neighborhood is seriously affected. The patient's meager allowance was completely withdrawn when the parents discovered he was spending it on candy. He met the situation and the need for status at first by employment in a job delivering papers. This, however, did not last long. Subsequently, he heard from another boy that it was a simple matter to walk into a store and drop articles into a shopping bag. After a time, he began taking things in this manner and sold them for small amounts to other boys in the neighborhood. He justified such actions on the grounds that the store owners were wealthy people who would never miss the few articles he took.

In this boy, of good physical development and health, with fine intellect, with excellent academic adjustment, we observe reactions to profound emotional tension. He is fully aware of the great difficulties which his parents have in meeting the cost of living. He admires his father for his devotion to duty and his mother for her self-sacrifice. He cannot justify taking advantage of their small store of funds. A growing resentment has developed over the family's deprivation, which, by comparison with his neighbors, is great. This resentment is directed towards the well-to-do and expresses itself not only in the small thefts but also in the damage to property and the expression of hostility which is so strikingly effected through the means of the stench bombs.

This child evidently feels set apart from others in the community, in effect has virtually withdrawn from the place which the family holds and which his older brothers and sister are carrying on. Unless his point of view and attitudes towards himself and others are very greatly changed, he may be expected to continue in the direction toward which these delinquencies point. Of greatest importance in therapy is an awareness on his part of the psychological motivation. To this end psychotherapy is indicated.

In summarizing, I should like to repeat that in nearly all organic diseases, important emotional factors exist and that the physician must be concerned with these. He must be concerned with the patient not only as an individual but as a whole being. In the process he must proceed from consideration of the patient into his immediate social contacts. The extent to which he must go will be evident only in his personal relationships. In the treatment of the sick patient, the emphasis must shift from the treatment of the disease to the treatment of the patient.

TREATMENT OF MENTAL DISORDERS WITH PHARMACOLOGICAL AND ELECTRICAL SHOCK METHODS

NATHANIEL J. BERKWITZ, M.D., Ph.D.
Minneapolis, Minnesota

SHOCK therapy is now widely recognized as an effective therapeutic measure in the treatment of certain mental disorders and is being used in one form or another in most of our leading institutions. However, its universal adoption is being retarded because occasional serious complications have been encountered in the more drastic methods which are commonly used. Insulin-hypoglycemic and metrazol-convulsive shock continue to be the most popular methods used, although encouraging results are claimed with picrotoxin, triazol and other pharmacological convulsive-shock therapies. Electrical-convulsive therapy was introduced two years ago with the purpose of avoiding some of the dangers encountered in pharmacological-convulsive treatment. Scores of European and American workers are now investigating its merits, but whether this type of therapy is safer than pharmacological shock treatment remains to be proved. In May, 1939, the writer[3] introduced faradic shock therapy, a safer form of treatment which appears to be producing results paralleling those obtained with the more drastic methods. Shock therapy is not only proving to be a valuable adjunct in the treatment of mental disorders, but it is also giving us important information helpful in clarifying our understanding of the mechanisms involved in various mental disorders.

Shock treatment has been developed empirically, and numerous hypotheses have been propounded in an attempt to explain how it is effective and when it should be used. When insulin shock therapy was first introduced a certain group thought that at last an effective chemical treatment had been discovered and that all of the previous psychological theories could now be discarded. Others argued that relapses were so frequent and the treatment so heroic that it could hardly be recommended unless more striking and lasting results were obtained. Still others continue to maintain an attitude of conservatism because some deaths have been reported and because irreparable damage to the brain has been demonstrated in severe and prolonged attacks of hypoglycemia, either induced or spontaneous. But the great majority of workers who have used pharmacological shock treatment continue to express enthusiasm with their results in spite of its drastic nature.

Disadvantages of Our Present Classification

To understand which types of mental disorders may be most benefited by shock treatment a consideration of our present form of classification is pertinent. In 1896 Kraeplin[25] offered a classification based on symptoms which, with very little modification, is still being used. This classification tends to regard various forms of psychoses as definite entities entailing certain prognoses. According to Meyer[26] Kraeplin himself admitted that the cause of mental disorders was unknown, that the course varied, that the outcome of many cases was uncertain and that no specific lesion was demonstrable. Until the underlying causes of mental illness are better understood, classification must be considered purely tentative and inconclusive. A classification founded upon uncertain premises may be useful in the description of group psychoses, but it is fraught with danger when applied to the individual case.

Freud[14] was the first to show that a close relationship exists between hysteria, the prototype of psychoneuroses, and schizophrenia. Jung[24] drew a striking parallel between dementia precox and hysteria. Pavlov[29] has offered considerable evidence to show that schizophrenia may be regarded as a marked degree of chronic hysteria. Bleuler[6] stated that one can demonstrate a schizoid type of reaction as well as a manic component in every person in extremely varying degrees, and it is simply a question as to which reaction predominates. In this country Meyer and Campbell have been leading exponents in showing the disadvantages of a symptomatological classification, and stress the necessity of regarding mental disorders as merely individual reaction types effected by environment. Meyer[26] points out the need of new and open concepts for practical work, research and the presentation of

the issue to student and laity alike. Campbell[8] says that we should utilize the concept of a schizophrenic reaction type as one accepts an hysterical, or an affective reaction type, as all are precipitated by emotional stress or by failure to meet life situations. The resulting psychoses are merely expressions of certain types of constitutional weaknesses. Constitutional weakness is due in part to inheritance and is also the product of poor life habits. Briefly stated, mental disease represents an exaggeration or a caricature of the individual's personality. The constitutional makeup of the patient prior to the onset of the psychosis has more bearing upon his prognosis than the presenting psychotic symptoms. Thus it is obvious that a symptomatological classification is unsatisfactory, and that a thorough understanding of the individual is necessary if one hopes to treat these patients effectively.

Use of Shock Therapy in the Past

Shock therapy is not a new procedure in the treatment of mental disorders. In the earlier methods unplanned fear and suggestion were apparently the active psychotherapeutic agents employed. It may be quite possible that the ancient practice of trephination was a primitive form of shock therapy. This operation was performed for mental disorders with the belief that "confined spirits" were allowed to escape. It was widely used, for neolithic skulls with discs of bones removed have been found in nearly all parts of the world.[28] Terror and fear as well as suggestion producing profound physiological changes of the nervous system must have prevailed during such operations. Benjamin Rush[31] in 1817 cited many cases of psychoses cured by fear. Deutsch[11] writes of various technics used from 1780 to 1830 to frighten the patient out of his psychosis. In 1828 Burrows[7] recommended that insanity might be cured by provoking fits with the administration of large doses of camphor.

During the past two centuries electricity was popular from time to time in the treatment of mental disorders. In the middle of the nineteenth century the use of electricity became so popular that Huff[21] remarked that mental illness should not be considered incurable until electricity in some one of its forms had been tried. Sir Clifford Allbutt[1] in 1872 made a systematic study of the use of electricity in the treatment of mental disorders. He used a continuous current, applied to the patient's head for ten minutes each day. Evidence of sympathetic nervous system stimulation such as "flushing of the face, giddiness, increased pulse rate and dilatation of the pupils" were noted in most of these patients. He observed marked improvement in acute primary dementia, distinct improvement, but to a less degree, in mania and recent secondary dementia, no change in chronic dementia and "brain wasting," and unfavorable results in hypochondriacal melancholia. Today few claim better results with current forms of shock treatment. Erb[12] discussed the vasomotor effects produced by electricity in an article written in 1883. It is of interest to note that he pointed out that vasomotor disturbances play a dominant part in the development and symptomatology of many forms of psychoses. In 1884 Haynes[19] observed that early functional diseases were benefited by electricity, whereas older and organic conditions showed no response. Blandford[5] in 1886 believed that the encouraging results obtained in mental disorders with electrotherapy were due to "moral" rather than to physical causes.

As a counterpart of the red-hot iron used in the middle ages, the Paquilin cautery has been used within our own generation as a form of shock treatment.[27] This instrument had a hollow platinum point which was kept hot by benzene vapor passing through it. In recent years many new experimental methods of shock treatment have been tried. Various types of induced fever therapies such as malaria, sulfosin and African tick fever have been tried, but results on the whole have been disappointing and inconclusive. Similar experience has been reported with foreign protein shock and leukogenic shock treatment. In the latter method fixation abscesses were produced by cutaneous injections of turpentine.

Janet[23] has regarded these forms of treatment as procedures by moral as well as physical means, or as "treatment by excitation." While admitting that some of these methods may have some merit he warned that exhaustion is a great danger in such therapy. With insulin-hypoglycemic and the various forms of convulsive shock therapies the patient is left in a comatose or unconscious condition whereby extreme apprehension or exhaustion is avoided. When subconvulsive doses of metrazol are given, the patients are left in an

excited and apprehensive state and unsatisfactory results are obtained by this procedure.

Current Theories of Shock Therapy

Although the use of shock treatment is increasing, differences of opinion still exist as to why it is effective. The theories advanced by Sakel have been criticized by Cobb[10] and Gellhorn.[16] A review[32] of Sakel's monograph recently published states, "the clinician will profit from reading the monograph provided he ignores the theoretical and considers only the factual part of the exposition." The theories advanced by Meduna have been attacked by Harris[18] and others.

Gellhorn[16] offered a theory that insulin, metrazol and other drugs used in pharmacological shock therapy benefit the patient by producing anoxia which stimulates the autonomic nervous system in the hypothalamus. Friedman[15] speaks of shock therapy as an irritative therapy which stimulates the central nervous system and breaks up "physiological barriers" to certain associative pathways. Bennet[2] suggested that the effects on depressive conditions are probably due to the efforts of the patient treated to prove to himself his willingness to undergo punishment, with a subsequent resolution of his guilty feeling. Some[22] believe that the shock treatment increases the metabolism in the brain by a sudden rise of the systemic blood pressure. It has been suggested by Querido and Van der Speck[30] that shock treatment does not make patients more social but merely more submissive. Many workers[33] maintain that fear alone is the main effective element. They speak of the patient's fear of the shock treatment as a fear of death or as a "threat of extinction." The frequent observation that psychotic patients temporarily lose their psychotic symptoms or improve when their life is threatened with an acute infectious illness or when subjected to a sudden emotional shock or a major surgical operation supports this theory.

In contradistinction to older medical views that a dichotomy of the mind and body existed, it is now generally agreed that there is a psychosomatic interrelationship between psychological and bodily functions through the medium of the autonomic nervous system. When an individual is unable to face the realities of life, emotional conflicts develop. These conflicts interfere with intricate adjustments necessary in life and the lower and automatic centers of control then assert themselves. Consequently the individual no longer has a harmonious and fully integrated behavior. A vicious circle becomes established and uncontrolled psychic reflexes tend to accentuate and prolong the newly acquired abnormal mental behavior. During the acute stage little can be done by the customary psychotherapeutic approach since the patient is often mute, unwilling or unable to coöperate. After the acute stage passes it is often too late to accomplish much by pleading with reason, for the patient has drifted into a reconstructed world and he is no longer able to cope intelligently with his daily problems. Cannon[9] stresses the futility of trying to argue patients out of their emotional reactions since the cortex has no direct control over the autonomic nervous system. For this reason interviews, explanatory talks and reassurances are usually found to be inadequate.

Gellhorn[16] has pointed out that pharmacological shock treatments act as a powerful stimulation to the autonomic nervous system. This is obviously true also in the different types of electrical shock therapies. Henry[20] says that the autonomic system elaborates the current feeling by a reflex mechanism whether a person is responding to external danger or to internal conflict. According to Singer[34] the presence of a psychosis always indicates a disturbance in this system. Therefore it appears that shock therapy through autonomic stimulation in some way dislodges hallucinations, delusions and other symptoms disturbing to the patient which occur in psychoses. The exact process by which this takes place remains obscure. Probably different factors operate in different cases depending upon the individual reaction types. In some cases shock therapy may act as a planned fear reaction which may bring about an interruption of abnormally established thought habits and permit a reorganization and readjustment of a more normal thought flow. Or the action of shock therapy may in a broad sense be likened to a form of counter-irritation. Undesirable habit thought patterns are forcefully replaced by a real and visible threat to the organism and through activation and motivation the patient is brought back to face realities. In some of the depressed cases it may bring relief from a feeling of guilt by their willingness to submit to shock therapy which they regard as a punishment. Other patients may summon all of their resources to

face reality in order to avoid further treatment. But the writer believes that "treatment by excitation" according to Janet's use of this term is the modus operandi in all forms of shock therapy. It must be emphasized, however, that additional means of psychotherapy such as explanation, reeducation and guidance in conjunction with shock therapy are necessary to procure the best results.

Comparison of the Current Forms of Shock Treatments

The writer believes that all forms of pharmacological and electrical shock therapies produce similar effects since all are psychophysiological methods. Two conditions are known to occur: (1) powerful stimulation of the autonomic nervous system, followed by (2) depression or temporary inhibition of the higher cerebral centers. Increased pulse rate, elevation of the blood pressure, dilatation of the pupils, flushing of the skin, and increased salivation are some of the evidences of autonomic nervous system stimulation. After this stimulation the higher centers are depressed or temporarily paralyzed by the resulting coma or unconsciousness in pharmacological and electrical-convulsive shock therapies.

In a search to find a safe and better controlled substitute for pharmacological and electrical-convulsive shock therapies, the writer devised a method which he believes can produce similar effects by safer means. For stimulation, a faradic current well within the margins of safety is used in place of drugs. This current is not strong enough to produce convulsions or irreversible physiological changes. Immediately following a brief series of electrical shocks which are applied to the patient's head, an intravenous barbiturate (pentothal sodium) is administered for a quick anesthesia. In non-communicative and stuporous patients, additional information regarding their condition may be obtained by using a subanesthetic dose of intravenous sodium amytal instead of pentothal sodium. By the use of either drug the higher centers are temporarily inhibited and the patient is left in a relaxed condition which is attained under better control than is possible with the other shock methods. An immediate improvement may be obtained in stuporous and non-communicative patients with intravenous sodium amytal alone, but this change is very temporary. A full description of the apparatus and technic of faradic shock therapy has been published.[4]

In all methods it appears that best results are obtained when the personality is acutely and more or less totally involved and when the psychotic symptoms are decidedly unpleasant to the patient. In so-called catatonic and paranoid types of schizophrenia the results are far superior to those obtained in the simple and hebephrenic types. In the more chronic forms an adjustment is usually made at a lower level of mental activity. After six months to two years it appears that the psychotic symptoms become less disagreeable to the patient, and consequently they are less likely to respond to shock therapy. In the affective disorders the depressed types respond far better to shock therapy than the hypomanics and manics for these latter types usually retain a keen awareness of their position and environment and have fewer unpleasant symptoms which annoy them. Most dramatic results are obtained in acute hysteria for recovery usually takes place with the first treatment with convulsive or faradic therapy. The chronic forms of psychoneuroses are not greatly benefited by shock therapy. In these individuals the personality is partially involved over a long period of time and they have been in the habit of making only partial adjustments. Temporary results are obtained in this group after the first few shock treatments are given, but lasting results can hardly be expected since most of these patients do not want to get well emotionally, thought they may want to intellectually.

The relative efficacy of the different types of shock therapies remains to be established. Since mental disorders are not definite entities and in each case many complicating conditions exist, this question will not be answered until extensive statistical studies of the different methods are carried on over a considerable period of time. More rapid response is noted with metrazol, electrical-convulsive and faradic shock than with insulin hypoglycemic shock treatment. Improvement is usually noted within the first five treatments whereas with insulin-hypoglycemic shock the response is more gradual and a longer series of treatments is usually required. Some workers[35] have found that catatonic excitement and paranoid types react more favorably to insulin while stuporous patients respond best to metrazol. Others[17] believe that results with metrazol

closely parallel those with insulin. They recommend that metrazol treatment be given first since it is less expensive, for it requires less time to administer. Some[13] recommend combining or alternating these methods. The writer believes that the least drastic method (such as faradic shock) should be tried first. If the results are not favorable other methods may then be used. Using faradic shock therapy the writer obtained relatively as favorable results in all types of mental disorders as those claimed with other forms of shock treatment. With faradic shock treatment improvement is usually noted after the second or third treatment. This treatment is as inexpensive to administer as any of the shock treatments now in use.

All forms of shock treatment should be considered merely as an adjuvant to psychotherapy. Other forms of psychotherapy are essential. Shock treatment may relieve the patient of acute psychotic symptoms, but it does not materially alter his constitutional makeup. For this reason it is understandable why relapses may occur among patients who have had remissions through shock therapy as well as among those who have had spontaneous remission. But it has been found that many patients who have relapsed after shock therapy frequently respond to further treatment. When remissions are brought about by shock therapy the ultimate prognosis may be more favorable, since by terminating the psychosis abruptly through a specific means a better opportunity is offered to explain to the patient how his mental illness came about and to point out how further recurrences may be avoided.

Summary

Since insulin-hypoglycemic shock therapy was first introduced, several different forms of pharmacological and electrical shocks methods have been tried. The effectiveness of many of these shock treatments in mental disorder is now generally conceded but a search continues for safer methods.

Shock therapy is not a new procedure. It was used in many crude forms for centuries but one of its chief dangers was creation of exhaustion.

In the current forms of shock treatment two conditions are known to occur: (1) stimulation of the autonomic nervous system, followed by (2) inhibition of the higher centers. The former condition acts as a "treatment by excitation" and the latter prevents exhaustion. Similar conditions are produced under better control with faradic shock therapy and comparable results are more safely obtained. Its use is recommended before resorting to more drastic methods.

No form of shock therapy can be expected to alter materially the original constitutional makeup of an individual but it may remove acute and unpleasant psychotic symptoms.

Shock treatment should be regarded as an adjuvant to psychotherapy and for best results other psychotherapeutic procedures commonly used are essential.

FEEDING THE PREMATURE BABY*

ALBERT V. STOESSER, M.D.

Minneapolis, Minnesota

THE care of the premature infant is one of the most fascinating problems in medicine. More and more interest in their care has been shown by the medical profession. It is a thrill indeed to see one of these tiny shrivelled dusky mites transformed into a healthy infant in a matter of weeks. Their progress is so rapid if they are properly treated that one can see the change in them from day to day and although the care they demand is much more time-consuming and specific than a normal newborn baby, the satisfaction derived from their progress fully repays one.

This discussion is intended primarily for the practicing physician who has but occasional use for information on the premature infant. Recently more requests have come for information on feeding than any other phase of premature care, and feeding, while no more important than any of the other phases, is perhaps the most difficult part of their care because it needs superpatience and care on the part of the attendants as much as promptness and exactness.

Taking it for granted that the physician is able to cope with the problems of keeping an ideal temperature and humidity for the baby and that an adequate isolation or aseptic technic has been set up to prevent upper respiratory and skin infections, the feeding problem can take our entire time.

The infant is not disturbed for feeding for a period of 16 hours or more after birth. This rule is not changed under any condition. The temperature of the bassinet is regulated as necessary to accommodate the baby's temperature. The admission temperature of the crib is always 100° F. but it is seldom necessary to have it that high for more than 2 to 4 hours and thereafter it is gradually lowered so that after a period of 24 to 48 hours the crib temperature is adequate when kept at 86° F.

Although the foremost aim of this 16-hour period is complete rest, the infant's temperature must be checked every 2 hours while the crib temperature is high, and his general condition must be watched closely especially for respiratory difficulty.

If the baby's condition is good after 16 hours have elapsed, feeding is begun. If, however, the infant's condition is poor, the rest period is continued for another 4 to 8 hours or until the baby has improved.

As in full term infants, the premature baby has a loss of weight during the first few days of life. However, the loss in a premature infant is relatively greater than in a newborn and is regained more slowly. The loss in weight should not average more than 7 to 8 per cent of the birth weight.

After the first few days, the total fluid intake should be maintained at from one-sixth to one-eighth of the body weight in each 24 hours. The sum of the water and milk intake determines the total fluid intake.

A good method for obtaining the required fluid intake during the first few days of life is to give subcutaneous fluids. Hartmann's solution or Ringer's solution may be used. The needles (20 gauge intravenous) are inserted into the inner aspect of the thigh just above the knee and passed toward the midpoint of the inguinal ligament. This should be administered very slowly, preferably by continuous drip. For a small premature, that is one weighing less than 1,500 grams (3.3 pounds) 50 to 75 c.c. of the solution is sufficient. This is given the third day

*From the Pediatric Division at the Minneapolis General Hospital and the Department of Pediatrics, University of Minnesota. Chairman's address at the Round Table Discussion on the Care of the Premature, presented at the eighty-seventh annual meeting of the Minnesota State Medical Association, Rochester, Minn., April 23, 1940.

and may be repeated daily if the baby is taking fluids poorly. Premature infants over 1,500 grams (3.3 pounds) to 2,000 grams (4.4 pounds) may be given 75 to 100 c.c. of the solution and those babies weighing more than 2,000 grams may be given 100 to 125 c.c. of the solution. Usually if an infant weighs more than 1,500 grams (3.3 pounds) only one subcutaneous injection is necessary, but the very small babies frequently need two or more.

In addition to fluids, whole citrated blood may be administered to the premature infant with beneficial results. This is most frequently given the day before subcutaneous fluids are started (during the second 24 hours of life). When this procedure is performed, 10 c.c. (⅓ ounce) are given to the small babies (1,500 grams or less in weight) and up to 30 c.c. (1 ounce) to the larger babies. The procedure is a simple one. A 3-inch No. 19 or 20 gauge infiltration needle is introduced into the subcutaneous tissue in the kidney region of the back. The needle is inserted deeply and passed up parallel to the spinal column to the sub-scapular region. As the needle is withdrawn, the blood is injected leaving a column of blood almost the length of the back. The needle puncture point is sealed with collodion on a small piece of cotton. Blood is injected on both sides of the midline. If the infant is placed on his abdomen over a small blanket roll so that the back is slightly arched, the blood may be injected with little difficulty.

The feeding schedule is a controversial point among many pediatricians. Some doctors advocate frequent small feedings; others give larger amounts with longer intervals between feedings, The latter method has one important advantage in that it gives the baby more rest. Both methods are successful if used intelligently. At the Minneapolis General Hospital the 4-hour schedule has been used for the last 8 years successfully.

The prematures are divided into three groups according to their weights: the first group is made up of those weighing 1,500 grams (3.3 pounds) or less, the second group includes those between 1,500 grams and 2,000 grams (4.4 pounds) and in the third group are those weighing 2,000 grams or more.

After the 16-hour rest period the first group is offered 10 c.c. (⅓ ounce) of water every 2 hours during the remainder of the first day and thereafter every 4 hours. After the first 24 hours the amount of water offered is increased by 2 c.c. with each feeding until 30 c.c. (1 ounce) are reached, and this amount is continued until the tenth day. After 10 days one ounce is given twice a day at 8:00 A.M. and 4:00 P.M. If the baby has difficulty taking fluids by mouth, the water is discontinued and given subcutaneously.

Milk feedings are begun at the end of the first 24 hours. Beginning with 5 c.c. of breast milk with 2 per cent calcium caseinate (Casec) every 4 hours, the amount is increased by 1 c.c. with each feeding until 50 c.c. (1⅔ ounces) are offered. Further increase in feeding depends upon the progress of the infant. Usually the feeding may be increased from 2 to 5 c.c. per day thereafter. If any regurgitation takes place, the amount is immediately decreased.

The second group is also given 10 c.c. (⅓ ounce) of water at the end of the 16-hour rest period, and this amount is repeated every 2 hours for the remainder of the first 24 hours. Thereafter water is given every 4 hours and with each administration the amount is increased by 2 c.c. until 45 c.c. (1½ ounces) are reached; then decreased by 2 c.c. until 30 c.c. are reached. This is continued until the tenth day. After ten days an ounce of water is given only twice daily as in group one.

Beginning at the end of 24 hours, 10 c.c. (⅓ ounce) of the milk feeding are given. As in group one these feedings are given every 4 hours (at the alternate 2-hour period water is given), increasing the amount by one c.c. with each feeding until 60 c.c. (2 ounces) are reached. Further increase is ordered as the baby demands it which is usually about 5 c.c. per day until 3 or 4 ounces have been reached.

Prematures in the third group are started with 15 c.c. (½ ounce) of water at the end of 16 hours. This amount is given every 2 hours until the end of the first day. Thereafter the water is given every 4 hours increasing with each administration by 2 c.c. until 45 c.c. (1½ ounces) are offered; then decreased by 2 c.c. each feeding until 30 c.c. (1 ounce) are given. At the end of the tenth day 30 c.c. of water are given only twice daily at 8:00 A.M. and 4:00 P.M., just as the first and second groups.

At the end of 24 hours the third group is offered 15 c.c. (½ ounce) of milk feeding. This feeding is given every 4 hours (at alternate hours with the water) increasing the amount

by 2 c.c. with each administration until 45 c.c. (1½ ounces) are given. The amount is then increased by 5 c.c. a day until 75 c.c. (2½ ounces) are reached. Additional increase in the feeding depends upon the progress of the infant. In most cases the feeding can be increased by 5 c.c. daily to 105 c.c. (3½ ounces). Babies weighing over 2,250 grams may require more food than is indicated in the above routine. If the infant will take more formula, the amount may be increased more rapidly.

Little can be expected in the way of weight gain until about 45 calories per pound (90 calories per kilogram) are administered. Later the infant may require as much as 60 calories per pound. Rather than to pay too much attention to total calories, a factor which has in the past been over-emphasized, it is a good plan to feed the premature infant an amount sufficient for an adequate consistent weight gain.

For the sake of clearness, the schedule is presented as follows:

ROUTINE OF FEEDING FOR THE PREMATURE INFANTS

	Milk—c.c.			Water—c.c.*		
	1	2	3	1	2	3
First Day:						
16th hr.				10	10	15
18th hr.				10	10	15
20th hr.				10	10	15
22nd hr.				10	10	15
Second Day:						
1st F.	5	10	15	12	12	17
2nd F.	6	11	17	14	14	19
3rd F.	7	12	19	16	16	21
4th F.	8	13	21	18	18	23
5th F.	9	14	23	20	20	25
6th F.	10	15	25	..	..	..
Third Day:						
1st F.	11	16	27	22	22	27
2nd F.	12	17	29	24	24	29
3rd F.	13	18	31	26	26	31
4th F.	14	19	33	28	28	33
5th F.	15	20	35	30	30	35
6th F.	16	21	37	..	..	..
Fourth Day:						
1st F.	17	22	39	30	32	37
2nd F.	18	23	41	30	34	39
3rd F.	19	24	43	30	36	41
4th F.	20	25	45	30	38	43
5th F.	21	26	50	30	40	45
6th F.	22	27	50	..	..	..
Fifth Day:						
1st F.	23	28	50	30	38	43
2nd F.	24	29	50	30	36	41
3rd F.	25	30	50	30	34	39
4th F.	26	31	50	30	32	37
5th F.	27	32	50	30	30	35
6th F.	28	33	50	..	..	..
Sixth Day:						
1st F.	29	34	55	30	30	33
2nd F.	30	35	55	30	30	30
3rd F.	31	36	55	30	30	30
4th F.	32	37	55	30	30	30
5th F.	33	38	55	30	30	30
6th F.	34	39	55	30	30	30
Seventh Day:						
1st F.	35	40	60	30	30	30
2nd F.	36	41	60	30	30	30
3rd F.	37	42	60	30	30	30
4th F.	38	43	60	30	30	30
5th F.	39	44	60	30	30	30
6th F.	40	45	60	..	..	..
Eighth Day:						
1st F.	41	46	65	30	30	30
2nd F.	42	47	65	30	30	30
3rd F.	43	48	65	30	30	30
4th F.	44	49	65	30	30	30
5th F.	45	50	65	30	30	30
6th F.	45	51	65	..	..	..
Ninth Day:						
1st F.	46	52	70	30	30	30
2nd F.	47	53	70	30	30	30
3rd F.	48	54	70	30	30	30
4th F.	49	56	70	30	30	30
5th F.	50	58	70	30	30	30
6th F.	50	60	70	..	..	..
Tenth Day:						
1st F.	50	60	75	30	30	30
2nd F.	50	60	75	30	30	30
3rd F.	50	60	75	30	30	30
4th F.	50	60	75	30	30	30
5th F.	50	60	75	30	30	30
6th F.	50	60	75	..	..	..
Eleventh Day:						

Further increases in feeding depend upon progress made.

F.—Feeding.
1—Prematures 3.3 lbs. (1,500 grams) or less.
2—Prematures 3.3 and 4.4 lbs. (1,500—2,000 grams).
3—Prematures 4.4 lbs. (2,000 grams) and more.

*If specified amount of water cannot be taken orally, give it in small doses, subcutaneously as physiological or isotonic saline.

The feeding most easily assimilated by the premature baby is human milk. The mother should be taught by the doctor or a competent nurse to express her breasts as soon as the milk comes into them. If this procedure is carried out correctly and conscientiously every 4 hours, 5 times in 24 hours, her breasts will stay stimulated and give an adequate milk supply for her baby. If the mother is unable to produce enough milk, an effort should be made to obtain it from some other source at least until the baby weighs 2,500 grams. The milk collected over a period of 24 hours is boiled 1 to 2 minutes and 2 per cent Casec is added to it. The addition of calcium caseinate (Casec) has been found to definitely reduce the number of cases in which frequent liquid stools have developed and has led to a satisfactory and consistent gain in weight. As long as the amounts are graduated,

each feeding should be poured into a separate bottle and labeled with the amount and the time that the feeding is to be given.

Because economic and physical conditions often make it impossible for the physician in a small community to obtain breast milk, scientific investigations have been made with the result that a preparation has been formulated which is an adequate substitute. The observation that premature infants have low values for serum protein during the first 3 months of life led some physicians to experiment with the addition of protein content to the milk feeding for the premature baby. It was finally discovered that the simple fortification of cow's milk with 1 to 3 per cent calcium caseinate gave the most satisfactory results. Extensive studies have been made in the fat metabolism of normal, premature and twin infants. It was found that premature babies did have marked difficulty in fat absorption. There was also striking differences in the ease with which the different fats were absorbed. Olive oil was more completely absorbed than butter fat, and thus when olive oil was substituted for butter fat, there was a more rapid gain in weight. A product containing both calcium caseinate and olive oil was developed. This product (Olac) is made up of skimmed milk solids, calcium caseinate, olive oil, and dextrimaltose. In view of the fact that vitamin A is removed when the cow's milk is skimmed, halibut liver oil is added. Olac with which no doubt a number of you are already familiar comes in powder form. It is simple to prepare: one part of Olac is slowly added to 5 parts of sterile water. In a study made at the Minneapolis General Hospital in which Olac was compared with the breast milk-casec formula and with an evaporated milk formula, it was found that it compared favorably with the breast milk formula in that it was easily assimilated by the infants weighing 2,000 grams (4.4 pounds) or less, and surpassed the evaporated milk formula. As for the larger infants, those weighing over 2,000 grams (4.4 pounds), the group that received Olac made a better showing than either of the other two groups which were fed the breast milk and the evaporated milk mixture. Because of the added cost of this product the babies are often placed on an evaporated milk formula which they can tolerate more easily as they mature. If the premature babies are given Olac until they are the weight of normal newborn babies, it is usually sufficient.

In the presence of loose stools which in our experience is comparatively seldom, 2 per cent Casec added to the Olac, gives a good response.

The evaporated milk formula is made up of equal parts of evaporated milk and sterile water with 3 per cent dextri-maltose. Although it is assimilated less easily than those already discussed, it has given good results especially in the larger premature babies.

Feeding the premature baby is one of the major considerations in the nursing care. Every precaution must be taken to insure cleanliness in the preparation of feeding and fluids, and it is essential that feedings be kept warm throughout the time they are being given. Three methods are commonly employed:

1. The gavage or catheter method is frequently used.
2. A medicine dropper protected by a rubber tip may be used. If correctly employed it is a good method, but it is harder than other methods to teach to the personnel.
3. Bottle feeding is used but conservation of the baby's strength is here to be considered.

Gavage is done to conserve the strength of the very small infant. Too often it is employed only as a time-saving measure. As irritation and injury to the nasal mucosa may result from nasal gavage, the oral route is preferred. Many babies weighing less than 4.4 pounds (2,000 grams) must be fed by catheter. If this is necessary, a No. 10 French catheter is used for small prematures; a No. 12 French catheter for larger prematures. The length of catheter to be passed is measured as the distance from the tip of the ensiform cartilage to the bridge of the nose. It may be marked at this point with silver nitrate. The average length is 4 to 5 inches, which will bring the tip of the catheter just to the cardia of the stomach. The catheter is moistened with water before passage. The sterile catheter or tube is carefully passed by mouth, not allowing it to go beyond the mark. There should be a catheter for each infant. The baby may be supported in a semi-recumbent position, and after becoming quiet is slowly fed. When the procedure is complete, the tube is kinked and removed quickly. The infant is supported in the sitting

position, in the crib, to allow for the expulsion of air. The baby is watched carefully at the time of feeding and for a while after the tube is removed to see if it is going to regurgitate. If regurgitation should occur, the head and shoulders are lowered and the baby is turned face downwards. As soon as the infant has been tube-fed, it is turned to the right lateral position. This nursing care is one of the most important factors in preventing otitis media and bronchopneumonia due to aspiration.

Infants weighing over 4.4 pounds (2,000 grams) may often be fed by medicine dropper which is considered by many to be the method of choice. Patience and care on the part of the nurse are prerequisites to success. Drop by drop the fluid is placed on the dorsum of the tongue, trickles down and is swallowed. To avoid aspiration of feeding it is essential that the nurse support the infant in a semi-sitting position and before replacing him flat on the mattress she must inspect his mouth and throat to determine that all the feeding has been swallowed. Babies usually begin to nurse from the bottle when they approach 5 pounds (2,300 grams) in weight.

Premature babies give signs of vitamin deficiency early in life unless their diets are well fortified with the essential ones. Vitamins aid greatly in the progress of the infants and it is wise not to let more than two weeks elapse before they are added to the diet.

Ten drops of a water soluble antirachitic preparation (Drisdol) may be added twice daily to the formula of the babies weighing less than 2,000 grams (4.4 pounds). One teaspoon of fresh orange juice may also be given twice a day. If the baby does not take fluids well by mouth, the orange juice may have to be given by the gavage method. When the babies reach or are 2,000 grams (4.4 pounds) or more in weight, they may receive Oleum Percomorphum (50 per cent), White's Cod Liver Oil Concentrate, or Viosterol in Halibut Liver Oil. Ten drops of any one of these preparations should be given twice a day in a small amount of orange juice. Cod Liver Oil or concentrates (oily preparations) should not be added to the formula since a large proportion of the oil sticks to the bottle and the nipple. The amount of orange juice can be increased gradually from 1 to 2 teaspoons twice a day.

In connection with feeding, one is faced with three complications common to premature babies. They are persistent regurgitation, vomiting, and diarrhea.

Regurgitation may often be simply corrected by intelligent nursing care, that is by feeding more slowly and carefully, by elevating the baby's head while feeding, or by placing the baby in a semi-sitting position when half the feeding has been taken, and again when it has been completed, to allow the baby to belch. It may be too that the baby is being overfed, and that his spilling over can be corrected by decreasing the feedings temporarily, then slowly increasing after regurgitation has ceased. When vomiting occurs no further increase in feeding should be made. It may actually be necessary to stop the formula for one or two periods, or at least to decrease the volume and increase the number of feedings until the vomiting has stopped. The physician must determine this in each case.

If diarrhea (water stools) occurs, the first and most important consideration must be an increase in fluids. The simplest method of doing this is to give Hartmann's solution by hypodermoclysis. The formula is discontinued for 1, 2 or 3 feedings, after which they may be resumed by using small amounts of an easily assimilated food, and gradually increasing the volume to requirements. The breast milk-calcium caseinate preparation or Olac with the addition of calcium caseinate are best employed in these cases. Weak tea or one-half strength Hartmann's solution may be given by mouth in the interval when no milk feeding is used. All antirachitic and antiscorbutic therapy should be discontinued while either diarrhea or vomiting exist.

If there is no improvement in the diarrhea, whole blood may be given deep subcutaneously. Intravenous therapy though usually difficult to perform, is most effective in this situation. The Hartmann's solution given by slow continuous administration, about 3⅓ ounces (100 c.c.) to small infants and as much as 6 ounces (200 c.c.) to the larger premature infants, may be repeated daily until the baby is able to take adequate fluids by mouth.

During a siege of vomiting or diarrhea the infant should be weighed daily so that its course may be watched closely. If there is a weight loss, concentrating the breast milk two-thirds

(Continued on Page 70)

HISTORY OF MEDICINE IN DAKOTA COUNTY

(Continued from December issue.)

1890-1900

The cost of the medical attendance on the poor mounted during the nineties. In 1894 the physicians of the county offered to do all of this work for the sum of $1,500. This proposition was refused by the commissioners because it seemed too expensive. Nevertheless a rough estimate of the bills sent in by the individual physicians for that year shows that the county saved, at most, only a few hundred dollars. The following year the total cost was well over $1,700. As a result the county was divided into specific districts, each of which enjoyed the services of a physician at a fixed salary. In this way the total was kept at approximately $1,100 per annum. The districts were as follows: (1) Hastings, Ravenna, Nininger, the north half of Marsham and the east half of Vermillion; (2) New Trier, Hampton, Randolph, Douglas and the south half of Marsham; (3) poor farm, Rosemount, Lebanon, and west half of Vermillion; (4) Lakeville, Eureka, Burnsville, Greenvale, Waterford, Scotia; (5) Farmington, Empire, Castle Rock; (6) South Saint Paul, West Saint Paul, Inver Grove, Eagan and Mendota. Almost every reputable physician at one time or another served in the capacity of county physician.

The position of health officer in Hastings was filled by J. C. Fitch, Peter Schneider, J. J. Schmitz, A. M. Adsit, and H. G. Van Beeck. The third name in the list is that of a veterinary. At the time of his election in 1897 the mayor announced that the salary of the health officer would be $100 for the year "if he attended to his duties." Previously the salary had been less than this. There is nothing to indicate that the health officers were not in the habit of "attending to their duties." They reported births and deaths, saw that the city was cleaned up every once in a while, checked up on the contagious diseases in town, advised the muzzling of dogs, and on several occasions suggested better ventilation and more blankets for the city jail. The reports were usually "accepted and placed on file" by the city authorities.

Members of the pension examining board in the nineties were Dr. J. M. Tucker and Dr. H. G. Van Beeck. Dr. Van Beeck and Dr. J. C. Fitch did most of the examining of the insane in the county.

Among the first and best known of the physicians who opened offices in the county during this decade were Peter Schneider of Hastings, and W. H. Cooke of Lakeville. Dr. A. A. Finch and Dr. A. B. Hawes both practiced in Hastings with their fathers for short periods. Others who came a little later were Drs. R. E. Cavanaugh, Wm. M. Dodge, J. G. Hodgkinson, A. O. Beal, A. G. Phelps, F. H. Ford, Charles Cappellen and C. A. Faulkner. Most of the latter group did not remain in the county

As in the preceding decade the only diseases that affected the community to any extent were scarlet fever and diphtheria. There was a slight alarm caused by the former in November, 1895. As to diphtheria there were a number of cases

almost every year and the toll of deaths, although not long, was, nevertheless, steady. The local health officers showed themselves to be active in quarantining cases and giving instructive lectures. In December, 1899, a special meeting of the Hastings city council was called at the instance of the board of health to devise means of controlling the diphtheria cases in town. The following regulations as printed in the *Hastings Gazette*, December 9, 1899, were adopted:

1. All cases of sore throats reported to the health officer to be temporarily quarantined.
2. All people found endeavoring to evade the law to be prosecuted by the health officer.
3. Three physicians to be engaged to visit the schools daily and all suspicious cases to be temporarily quarantined and a swab taken for examination.
4. These physicians to ascertain the condition of health of all absent children in their respective schools.
5. Health officers to enforce the quarantine according to the law.
6. The three physicians appointed to report daily to the health officer.

While efficient physicians adopted up-to-date theories and methods, many an old-timer in the country continued to practice on the basis of his practical experience, as he had learned little or nothing since he left medical school some thirty or forty years before. Such for example, was Dr. Percival Barton, an able practitioner, but a confirmed enemy of all new theories. It is rather pathetic to find him, as late as 1895, writing an article for the *Northwestern Lancet* in which he assailed the germ theory, maintaining that bacteria are the result and in no case a cause of illness.

Biographies

E. D. Abell came to Farmington about 1878 and practiced there for many years.

Charles Powell Adams, one of the outstanding men of Dakota County, was born in Pennsylvania in 1831. He was of Scotch-English and German descent. At the age of eighteen he began to study medicine with Dr. W. R. Waddell of West Bedford. He also studied in Knox County, Ohio, with Drs. Connelly and Pierce, and graduated from the Ohio Medical College in 1851. The next year he began practice in Indiana but his health was impaired by overwork and an attack of malaria and he moved to Hastings. In 1859, Dr. Adams bought a grocery store which he ran for a number of years and about the same time he began the publication of a newspaper, the *Hastings Democrat.*

In May, 1861, Dr. Adams enlisted as a private in the Dakota County Volunteers and was elected captain of his company. He was promoted the next year to the rank of lieutenant-colonel in the First Minnesota Regiment and in March, 1865, he was made a brigadier-general. We take the following paragraph concerning his war experiences from Neill and Williams' history of Dakota County:

"He was in every battle from the first Bull Run to Gettysburg, and was an unusual sufferer from wounds. His first wound was a slight one in the left groin, at Malvern Hill, July 1, 1862; at Antiatam, September 17, 1862, severely in the left shoulder; at Gettysburg, July 2, 1863, six times, through the left cheek and left lung, in the groin, in the left thigh, breaking the femur, and one in the abdomen. He was left for dead on the field, but was found and cared for by his comrades and was taken to the hospital at Littlestown and thence to Baltimore, Maryland. For eighteen months a crutch was necessary to enable him to walk, and, as relics of the conflict, he carries in his body two bullets and one buckshot."

After the close of the Civil War, Dr. Adams commanded a corps of cavalry and artillery against the Sioux in 1866 and was successful in spite of the heavy snow and cold weather. In 1877 he was elected president of the newly organized Dakota County Veteran Association.

Dr. Adams was a charter member of both the Minnesota State Medical Society (1869) and the Dakota County Medical Society (1870) and held offices in both organizations. He was affiliated with the American Medical Association, attending many of its meetings, an honorary member of the California State Medical Society, a member and ex-president of the Rocky Mountain Medical Society.

Dr. Adams was active in local and state politics and was a member of the Democratic party. In 1856 he was elected a member of the territorial legislature and was appointed chairman of the committee on corporations. He served as mayor of Hastings in 1873 and in 1878 was elected a member of the state senate from Dakota for a four-year term.

Dr. Adams was married three times. He died on his farm in Vermillion in 1893 at the age of sixty-three.

Alfred Adsit was born in 1857. He attended the Detroit Medical College, Michigan, and the Columbus Medical College of Columbus, Ohio, from which he graduated in 1881. After specializing in eye and ear work at the Massachusetts General Hospital of Boston he located in Hastings in 1885 where he remained until his death. In 1908, with Drs. Clark and Wall, he opened a private sanitarium there. He was house physician at the Hastings State Asylum, served on the school board and was a member of the state and national medical bodies. For a number of years he was health officer of Hastings and he also served as county physician.

J. L. Armington practiced in Hastings during the sixties and seventies with the exception of several years spent at Northfield, Minnesota, and in Utah. He was a surgeon in the Second Minnesota Regiment during the Civil War.

E. D. (or E. G.) Ault, a graduate of McGill University, Canada, came to Hastings to practice with Dr. J. E. Finch in 1868. About a year later he moved to Dundas, Rice County.

E. D. Ayres came to Hastings in the fifties. The first definite indication of his residence there is the appearance of his card in the *Dakota Weekly Journal* in May, 1856. He was also a wholesale and retail dealer in drugs.

Percival Barton was born in Maine and came to Saint Paul in 1853. Thence he went to Inver Grove where he practiced medicine and also operated a steam saw mill. Subsequently he took up a claim in Waseca County but returned after a year to Inver Grove where he remained. During the war he enlisted with the Seventh Minnesota Volunteer Infantry as assistant surgeon. He graduated from the University of Pennsylvania in 1849 but practiced under an exemption certificate. He served as county physician for a number of terms and he served his immediate locality as justice of the peace. He was an able and sympathetic country practitioner and he also gave much time to business interests.

(To be continued in February issue.)

President, Minnesota State Medical Association

President's Letter

OUR PLACE IN SOCIETY

TO the men of the medical profession in Minnesota, the new year of 1941 offers another opportunity to be of service to the people of this great commonwealth. At no time in history has it been so necessary to make ourselves cognizant of the vitally important place that we play in the life of the state as well as the economic well-being of the people as the present. We are a part of the people and subject to the same unrest in which they find themselves.

Someone has said that a building is only as strong as its foundation, and again, that a tree can only survive if its roots are deep-seated and strong. So our medical profession has the confidence of the great majority of the people because it has a solid educational foundation, and it has a deep, vigorous root in the affection of the people because of its strength of purpose.

Today we find our profession most necessary to the people, not only those specializing in the various branches of the work, but likewise those who find their places as general practitioners throughout the length and breadth of the state, administering to the individual in all strata of society, the wealthy, the middle-class and the indigent being given no preference.

Where is there another profession so necessary to the present military program, to industry, to sanitation? What other profession can control the health in the schools, both grade, college and university? I ask you, could the health boards or departments, the state sanatoriums, hospitals and penal institutions exist without the medical man? No, we have our place to fill as no other can. We are indispensable to the life of the people.

We must exercise the heritage left us by our predecessors. We must be the leaders, not the followers, in the disseminating of medical lore. We can well afford to coöperate with lay health movements, but should take the initiative by instituting their programs.

The good neighbor attitude should be prevalent in our relationships between ourselves; friendships should be lasting; the words "competitor" and "competition" deleted from our dictionaries.

Our medical world is organized on pure democratic principles. It is a privilege to belong to the American Medical Association, the Minnesota State Medical Association and our County Societies and to be a part of them by exercising our right of franchise, by lending our support to their worthy movements, making ourselves felt in their deliberations, using our officers to carry out our wishes, our committees to do our researches, our state office to help us when questions of procedure arise. While our work is scientific, we must live under and submit to economic laws.

We cannot stand still. American initiative will not allow it. Let the New Year be our opportunity to build our place in society to greater heights.

Volume 24 JANUARY, 1941 Number 1

THE NEW YEAR

WHAT 1941 holds for America is predictable only in part. The new year will see considerable disturbance in the routine of affairs, both economic and medical. Thousands of individuals cannot be uprooted and transplanted to other localities and occupations without disturbing the usual placidity of life. The enormous expansion of military and manufacturing organizations incident to preparedness plans will necessarily be accompanied by some confusion due to inexperience. We may as well face the fact that there will be some individuals who for various reasons will not step in line. Perhaps lack of coöperation will be more in evidence than if we were actually at war. Public opinion in a country at war tolerates no shirking. There is not as strong an urge in a preparedness campaign for a war that possibly may not materialize. We have had a valuable example in France, however, of a country not united in its defense program, although she knew her neighbor was working overtime to build up its war machine. The unions of France would not lengthen their weekly work schedule. France is paying the penalty now and is learning that there are things worse even than war.

Japan's alliance with the Axis countries and Russia instead of intimidating the United States as intended, only made very evident the need for defensive armament on a large scale. An important question for us to decide in the near future will be whether we prefer to meet this foreign combination at some future date, possibly alone, or at an earlier date in alliance with a powerful empire. We are not prepared to take either step at present and the need for a vigorous preparedness campaign is only too apparent. Production so far has not met expectations and needs.

The medical profession has its part to play in preparedness. It is clear that this should be the main job for the medical profession in 1941 and that all matters such as government suits and agitation for changes in the fundamentals of medical practice should be indefinitely postponed.

THE NATIONAL PHYSICIANS' COMMITTEE

THE National Physicians' Committee is beginning its second year of life. Over 8,000 physicians over the entire country have contributed to its support. It is doing a most important work in educating the public as to the achievements of medicine and the advantages of the present form of medical practice. It is essential to counteract undesirable propaganda for state control of medicine. This committee has objectives in influencing the public similar to those of our state association through the work of its various committees on legislation, public health, interprofessional relations and radio, but it is approaching them differently and on a nation-wide scale. It is doing work that the American Medical Association cannot do and maintain

the status under which it has operated since its organization some ninety years ago.

The following facts serve as a portrayal of the work done by the committee during its first year of existence:

1. Speeches at twenty state medical association meetings.
2. Approximately 500 county medical meetings.
3. The encouragement of physicians to appear as speakers at meetings of Chambers of Commerce, Rotary, Kiwanis, and other luncheon clubs, women's organizations and on local radio broadcasts.
4. Two double-truck advertisements in the *Saturday Evening Post.*
5. Approximately fifty full-page newspaper advertisements (These were placed under local sponsorship.).
6. The distribution of approximately 1,092,000 letters and more than 2,000,000 booklets and other printed matter.

We believe that a firm foundation has been laid for further progress. The influence exerted by the National Physicians' Committee is evidenced by what President Roosevelt stated at the dedication of the National Institute of Health, at Bethesda, Maryland. He said:

"Neither the American people nor their government intend to socialize medical practice any more than they plan to socialize industry. In American life the family doctor, the general practitioner, performs a service which we rely upon and trust.

"No one has a greater appreciation than I of the skill and self-sacrifice of the medical profession. And there can be no substitute for the personal relationship between doctor and patient which is a characteristic and a source of strength of medical practice in our land."

The great basic need, that of a liaison with the public has never been more pressing and important than it is at this time. Preservation of the pattern of American Medicine is dependent on the wider knowledge on the part of the public of the problems, methods, aims, and practice, and, to the extent possible, the philosophy of American medicine under our system of independent practice.

With proper support by the physicians of the country, the National Physicians' Committee, in conjunction with the A.M.A. and the component state medical associations, is in a position to be of great influence and to lay before the American people the ideals of American medicine, and what American medicine has accomplished.

Eleven and four-tenths per cent of the doctors of Minnesota, or a total of 351 individuals, have contributed toward the support of the national committee during the past year. It is of interest to note the percentage of contributing doctors in the following states:

Arizona—13 per cent
Idaho—15 per cent
Montana—12 per cent
Nebraska—10 per cent
Nevada—12 per cent
North Dakota—15 per cent
Oregon—13 per cent
Utah—16.5 per cent
Washington—17 per cent

There is no reason why Minnesota should not head this list in 1941.

This is an appeal to the physicians of Minnesota to contribute in 1941 as liberally as possible toward the support of this committee. This committee is depending on you and earnestly seeks your aid. Checks should be made out to Dr. N. S. Davis, III, and mailed to him at the Pittsfield Building, Chicago, Illinois, in care of the National Physicians' Committee.

F. J. Savage† and W. F. Braasch*

Correction.—In the editorial entitled "The Blood Bank" published on page 870 of the December issue of Minnesota Medicine, the authors should have appeared as Dr. J. S. Lundy and Dr. Thomas H. Seldon. Through a typographical error, Dr. Seldon's name was misspelled in the final printing.

STATE MEETING

The annual meeting of the Minnesota State Medical Association will be held at the Saint Paul Auditorium May 26, 27 and 28, 1941.

The committee on Scientific Assembly consists of Dr. O. W. Holcomb, Saint Paul and Dr. A. N. Collins, Duluth, surgical section; Dr. H. C. Habein, Rochester and Dr. W. H. Aurand, Minneapolis, medical section; Dr. J. W. Gamble, Albert Lea and Dr. W. H. Hengstler, Saint Paul, specialties. Dr. F. W. Lynch, Saint Paul, is in charge of local arrangements.

One afternoon will be devoted to medical phases of the national defense program.

The popular Round Table luncheons will be held Monday and Tuesday.

---

†Chairman, Minnesota Division, National Physicians' Committee.

*Acting Secretary and Member Board of Trustees, National Physicians' Committee.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

MEDICAL ECONOMICS IN MINNESOTA
1934-1941

After eight years of service to the Committee on Medical Economics as chairman and as editor of this section of MINNESOTA MEDICINE, Dr. W. F. Braasch of Rochester this year resigned his post to devote himself to the heavy and exacting duties of trustee to the American Medical Association. As an officer for many years of the Minnesota State Medical Association and particularly as chairman of this committee, Dr. Braasch has won nation-wide recognition for himself, for the work of the Committee and for Minnesota.

The occasion of his retirement would be one of great regret and great loss to Minnesota if it were not for the fact that he retains membership in the committee and his interest in its work is certain to remain close and loyal. His duties as trustee will keep him in close touch with economic and social developments in medicine all over the country and his advice and assistance will undoubtedly be willingly given to his colleagues in Minnesota.

When the Committee on Medical Economics was formed in 1934 federal relief for the unemployed was new, Social Security was only a phrase and the concept of federal grants-in-aid for health programs in the states was still strange and unfamiliar.

It was evident to forward-looking physicians, even then, that new currents were moving in the United States and that medicine would inevitably be drawn into the main stream of a new government paternalism unless a strong, wise and far-seeing resistance could be set up.

Subsequent years have seen that resistance develop and flourish. And it is due to the work of men like Dr. Braasch of Minnesota that the government still pauses well on this side of an invasion of the private practice of medicine and that its spokesmen are still loud in praise of the fundamental principles for which medicine in America stands—maintenance of high standards for education and practice, freedom from political control for the doctor and freedom of choice for the patient.

It is difficult for any of us to think back clearly, now, to that remote date of 1934. We are separated from it by more than years. The face of the world has changed since then and attention in the United States has shifted over night from social reform to a feverish preparation for the cataclysm of war which may at any time spread from Europe and Asia to the American continents. Wars are not eternal, however, even when they go on for thirty years or even for 100 years. In the end there is a breathing space. But what will be left of the practice of medicine as we know it now in the United States when that breathing space comes?

It is for the American physician to say. Only he is keenly aware of the medical values which may easily be sacrificed with a mere scratch of a defense coördinator's pen in the heat of a national emergency. Only he whose whole heart and mind are bent upon healing can be trusted to cherish and protect the future of scientific medicine in this period of convulsion and attack.

Thanks to our alert profession in Minnesota, to our watchful and farsighted Committee on Public Policy, our fine State Board of Health and to Dr. Braasch and his committee, Minnesota today stands at the top among the states in medical achievement, in the public health, in its relative freedom from quackery in medicine and in the absence of radical and dangerous legislative tampering with the practice of medicine.

To hold the place we have won and to meet the heavy new responsibilities of the future is the task we must assume today. No one committee can do it; but if all of us work together for the common good, the task will be done.

FOR RESERVE OFFICERS IN MINNESOTA

Problems of medical reserve officers are varied and difficult. Official information on what the reserve officer may expect in the way of advance notice before he is called to active duty—about protection on active duty—about possible safeguards for the practice he leaves for the term of that service—is not always easy to secure and sometimes it seems to be contradictory and uncertain.

The following information has been verified by the Committee on Military Affairs and may be relied upon, subject to emergency changes in regulations always possible in view of the unsettled international situation and defense needs at home.

"With or Without Consent"

1. Under the recent joint resolution passed by the 76th Congress, the President is authorized to order into active military service of the United States for a period of twelve consecutive months each, any or all members of any Reserve component of the Army of the United States with or without their consent, to such extent and in such manner as he may deem necessary for the strengthening of the national defense. If a sufficient number of officers do not indicate their availability, reserve officers must necessarily be ordered to duty. The oath of office taken by each member of the Reserve Corps is regarded as binding and will be taken at its face value in lieu of advance notice if the member is needed.

2. Corps area surgeons have been urged by the Surgeon General of the Army and the Committee on Medical Preparedness to avoid, if possible, stripping any community of needed medical service; but military needs come first and it is inevitable that civilian considerations will receive smaller attention.

Urged to Volunteer

To reduce as far as possible the number of reserve officers who must be called without their consent, all interns and residents are being urged to volunteer at once for a year of service. To do so may save them an interruption to their practice later on. Definite arrangements are being worked out whereby some medical school graduates may be assigned to service in a military hospital and this service may count toward certification for an examining board since, within the next three months, about 20,000 additional military hospital beds will be opened and physicians will be needed to man these military hospitals.

3. Reserve officers should forward their physical examination records to Corps Area Headquarters before they are called to active duty. Not a few have been discovered unfit for service after they had left their practices and made extensive arrangements to be absent for a long period of time.

4. The War Department will not accept any resignations from officers in the Reserve Corps who are above the rank of a captain, regardless of reasons, unless specifically authorized by the Secretary of War. Those who are below the rank of captain may resign if they have persons dependent upon them and their resignations may or may not be accepted according to the circumstances and the need.

5. Pay and allowances are presented in the following chart:

PAY AND ALLOWANCES

Grade	Annual Base Pay	Monthly Allowances			
		Rental Allowance		Subsistence Allowance (30 days)	
		With Dependents	Without Dependents	With Dependents	Without Dependents
Colonel	$4,000	$120.00	$80.00	$36.00	$18.00
Lieut. Colonel	3,500	120.00	80.00	54.00	18.00
Major	3,000	100.00	60.00	54.00	18.00
Captain	2,400	80.00	60.00	36.00	18.00
First Lieutenant	2,000	60.00	40.00	36.00	18.00

6. The annual base pay is increased at the rate of five per cent thereof for each three years of service up to thirty years. Full time will be computed for all periods during which men have held commissions as officers in the Army, Navy Marine Corps, Coast Guard, Coast and Geodetic Survey and Public Health Service or in the National Guard, Naval Militia and National Naval Volunteers or the Naval Reserve Force or Marine Reserve Force when confirmed in grade and qualified for all general service and with full time for all periods during which they have performed active duty under Reserve Commissions and with one-half time for all other periods in which they have held Reserve Commissions.

7. The Order to active duty places the recipient on duty immediately upon receipt and he must report on the date set to the post, camp or station for duty. Travel allowance will be made at the rate of eight cents a mile based on the shortest usual railway route to the station. The trip may be made by automobile but no special delay will be granted on that account.

8. Transportation for dependents will not be furnished by the government and reserve officers are warned that the housing problem at or within the vicinity of Army stations is likely to be acute so that it will probably be advisable to leave the family at home. In some cases, families of officers are definitely forbidden to follow them to their posts.

9. Uniforms and military equipment may be purchased at the first station.

In Case of Injury

10. Injury received or disease contracted in line of duty will entitle the reserve officer on active duty, to hospitalization, medical and surgical care and regular pay and allowances up to six months after the prescribed tour of duty and to necessary hospitalization, medical care and subsistence as long as necessary if the injury or illness requires it for a period longer than six months. The same allowances apply to injury incurred in travel to and from the station.

11. In case of death or disability in line of duty when ordered to active duty for a period in excess of 30 days, the reserve officer is entitled to the same pensions, compensations, retirement pay and hospital benefits as a regular army officer of the same grade and length of service.

12. The reserve officer ordered to active duty (except for training) is entitled to all the benefits of the pension laws existing at the time.

Regular Army Appointments

13. Appointments in the Medical Corps of the Regular Army will, in all probability, continue as at present through competitive examinations of reserve officers who have not passed the age of 32 years at the time of appointment.

For medical reserve officers, as for men selected in the draft, the law provides protection against foreclosure on real estate and other civil suits while they are on active duty, against loss of equipment or other articles purchased previously on the installment plan—though the law does not annul the obligation itself—and against eviction for non-payment of rent provided the rental is not more than $80.00 and the premises are used chiefly for a dwelling place for family or dependents. No protection is provided in the law against eviction from premises used for offices, but all reserve officers and any others who may be called to service are advised to make special arrangements, immediately, with landlords looking to their possible absence on duty. Such arrangements have already been made by a number of real estate and rental firms in Minnesota for convenience of physician tenants. In St. Paul, for example, the management of one large building has announced that offices of physicians and dentists called to active duty will be closed and left exactly as they are for a nominal rental, $5.00 a month, for the period of their absence from practice. Similar arrangements can undoubtedly be made elsewhere.

Minnesota Plan

No law can protect against loss of practice, of course, but many state medical associations have developed a variety of plans for keeping intact the practice of members called to active duty. Some of these plans seemed elaborate and unworkable to the Committee on Military Affairs, which studied the matter. A simpler plan was accordingly presented to the Council, at its meeting on December 15, for Minnesota. This plan was approved and is already being put into effect.

It calls for creation of a special list or "pool" of physicians who are not immediately eligible

for military service and who can be sent on locum tenens to act as substitutes for physicians called for military service.

The first step in the program will be a special plea to all reserve officers, regardless of their situation, and even if they have already asked for deferment, to make all possible preparations now for a call to duty.

The need for medical officers is acute. No requests for deferment will be heeded by the War Department unless they are given for grave reasons. The reserve officer may be called with very short notice or no notice at all if the need is urgent.

For those who are unable to make their own arrangements the list to be created by the Association will fill the gap.

To procure the names for this list a canvass of the entire Association is already under way. Letters have been sent to every member, to interns, residents and fellows and to all affiliate members of the Association urging all who are willing to accept a locum tenens under these circumstances to send their names immediately to the State Office.

Contract to Be Drawn

For many young men just entering practice and for many older men who are retiring from active practice this "pool" of names may afford a welcome opportunity for service.

A contract will be drawn up with the advice of the legal counsel of the Association to protect the interests of both, in case a man is sent from the "pool" to substitute for a medical officer called to duty.

For Relief from Dues

The question of whether dues of members going into the service should be remitted was also discussed at length by the Council at the December meeting. It was generally agreed by the Councilors that no members could be relieved entirely of the obligation of paying dues to the state society for two reasons: first, the constitution and by-laws of the Association make no provision whatever for retaining members on that basis; second, heavy drains are anticipated on the state budget and funds could not be spared for the purpose, even if the time-consuming process of changing the by-laws were undertaken, this year.

It was suggested, however, that members who remain in practice at home will almost inevitably benefit to some extent from the absence of men in service and they will undoubtedly be glad to pay the dues of absent colleagues as their contribution to defense.

Meetings to Be Called

Indeed, it was reported that some societies have already decided to pay both local and state society dues for their members on active duty out of society funds.

At the direction of the Council, therefore, a letter has already gone to all officers of local and district medical societies asking them to call a special meeting of their societies to act upon this matter. In smaller societies where funds are limited, it was suggested that members might be assessed for the amount necessary to pay these dues.

The number of reserve officers so far called is relatively small and, though more will be called before July 1, the amount of money required from each society will not, it is believed, be excessive.

Membership Important

Many reserve officers, particularly those holding commissions in the higher grades, will not need or desire relief from payment of medical society dues. All, however, will want to retain membership, not only to maintain their own position at home and the position of their organization, but also to enjoy privileges of membership wherever they may be stationed. It is also an established fact that the War Department attaches great weight to medical society membership and takes it into account in making all appointments and promotions in the medical services.

NEW YEAR'S RESOLUTION

(Monthly Editorial Prepared by the Medical Advisory Committee)

With the advent of 1941 your Medical Advisory Committee is impelled again to put before you clearly the importance of keeping accurate records. There is no single item more important in defense of an unjust malpractice suit than a well-kept clinical record. Whether treatment is carried on in the office, or in the hospital, it is your important duty to put in writing the treat-

ment administered, and the advice given to the patient. Particularly important is a notation, in your own handwriting, of the directions you give a fracture care, or a post-operative case, when it leaves your immediate care.

A careful notation as to the condition of the specific ailment, when the patient leaves your hands, may save embarrassment and trouble later. You are busy. You cannot be expected to remember the details of any individual case, and if you are called upon suddenly to defend yourself in a malpractice suit a well-kept clinical record, including dates, will prove a great help.

In hospital cases be sure to have a notation on the chart, in your own handwriting, if there is any unusual occurrence. If a patient falls out of bed; if there is a complaint about a hot water bottle; if there is a minor infection of some kind, and if there is any evidence at any time of anything other than the expected course of events, make a note of it, with the date, on the Progress Record of the hospital chart.

When the patient leaves the hospital make a notation, in your own handwriting, of the condition on discharge, and the instructions given. Do this yourself; do not rely upon the intern or the house physician to do it for you. This will save time and trouble as to identification of the record if it ever has to be taken into Court.

Your Advisory Committee is not pessimistic. It believes that medicine and surgery, as practiced in Minnesota today, are of the highest type. Unfortunately, however, no one of us is immune to unjust malpractice suits, and, therefore, it behooves all of us to keep accurate and complete records, which may be of inestimable help in time of trouble.

Let this be an important New Year's Resolution for 1941!

W.H.H.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

J. F. Du Bois, M.D., Secretary

Former Minneapolis Chiropodist Pleads Guilty to Practicing Healing Without a Basic Science Certificate

Re: State of Minnesota vs. Clayton E. May.
Re: State of Minnesota vs. Otto A. Burger

On December 6, 1940, Otto A. Burger, fifty-five years of age, entered a plea of guilty before Judge Luther W. Youngdahl of the District Court of Hennepin County, to an information charging him with the crime of practicing healing without a Basic Science Certificate. Burger was sentenced to a term of 3 months in the Minneapolis Workhouse, which sentence was stayed for a period of one year upon condition that Burger return to the State of California, where he was living at the time of his arrest. Burger was indicted jointly with Dr. Clayton E. May by the Grand Jury of Hennepin County on April 27, 1937, charged with manslaughter in the first degree following the death of a 25 year old married woman on whom, it was alleged, a criminal abortion had been performed. The authorities were unable to apprehend either defendant at the time. However, in 1938, the defendant May was arrested in San Francisco, California, charged with murder in the second degree following an alleged abortion on a married woman. May was convicted at San Fancisco, and on October 29, 1938, was sentenced to a term of 5 years to life for that crime. Burger was apprehended in California in the summer of 1940, and returned to Minneapolis for trial. The facts in the case indicate, however, that the abortion was actually performed by the defendant May and that Burger acted simply as a go-between, and made the arrangements for the criminal abortion, and suggested certain medication for the deceased.

Burger was a licensed chiropodist in Minnesota from 1917 to 1936, at which time his chiropody license was revoked for non-payment of the annual registration fee. Burger has never been licensed in Minnesota as a physician although he attempted, without success in 1927, to secure a Basic Science Certificate by exemption, claiming at that time, that he was a naturopath. The defendant May was formerly licensed to practice medicine in Minnesota. On May 23, 1934, he was convicted in Federal Court in St. Paul of "conspiring to harbor and conceal a fugitive from justice, the said fugitive being one John Dillinger." For this Dr. May was sentenced to two years in the Federal Penitentiary at Leavenworth. On February 9, 1935, Dr. May's license to practice medicine in the State of Minnesota was revoked.

License of Minneapolis Physician Suspended for Three Years

In the matter of the revocation of the license of Lewis Van Deboget, M.D.

On December 12, 1940, the Minnesota State Board of Medical Examiners suspended, for 3 years, the license to practice medicine held by Lewis Van Deboget, M.D., of Minneapolis. Dr. Van Deboget was charged with having procured, aided and abetted a criminal abortion upon a married woman. At the hearing, Dr. Van Deboget denied the charge, but a statement signed by Dr. Van Deboget on July 1, 1940, at the time of his arrest, was introduced in evidence. In this statement Dr. Van Deboget admitted that he had been paid $50.00 by the husband of the woman, and upon being asked what method he used to induce the woman to abort, he stated:

"I painted the womb with iodine—the outside of the neck of the womb."

The statement also showed that upon being asked why he painted the womb with iodine, Dr. Van Deboget replied:

"It would cause the womb to contract and cause it to expel anything that was in it."

Evidence was also introduced at the hearing indicating that Dr. Van Deboget had performed other abortions. Dr. Van Deboget's case was submitted to the grand jury of Hennepin County in July, 1940, but the grand jury did not indict him.

Dr. Van Deboget's license was suspended on a previous occasion for a period of 3 months because of the issuance of over 4,000 non-bona fide medical prescriptions calling for alcohol, whiskey and other alcoholic beverages. This suspension occurred on July 6, 1938.

Dr. Van Deboget was born at Grass Lake, Michigan,

in 1874, and graduated from Hamline University in 1909. He was licensed to practice medicine in Minnesota by examination in the same year. Until recently Dr. Van Deboget's office was at 1032 2nd Ave. S., Minneapolis.

License of International Falls Physician Suspended for Five Years for Drug Addiction

In the matter of the revocation of the license of Robert F. Werner, M.D.

The medical license of Dr. Robert F. Werner of International Falls, Minnesota, was suspended for five years on December 12, 1940, by the Minnesota State Board of Medical Examiners. Dr. Werner's license was suspended because of his habitual indulgence in the use of narcotic drugs.

A joint investigation of Dr. Werner's activities, conducted by the Federal Bureau of Narcotics, and the Minnesota State Board of Medical Examiners, disclosed that between June 8, 1938, and June 8, 1940, Dr. Werner had purchased an excessive amount of narcotic drugs. Notwithstanding an unusually large dispensing record, Dr. Werner had a large shortage. He finally admitted that he had diverted a portion of his supply of morphine to his own personal use, which average from 3 to 6 grains daily. Dr. Werner's narcotic record for the period of June 8, 1938, to June 8, 1940, is as follows:

Drug	Bought	Disp.	On Hand	Shortage
M. S. ¼ gr.	12000	4260	53	7687 — (¼)
M. S. ⅙ gr.	10900	4970		5930 — (⅙)
M. S. ⅛ gr.	7100	2840		4260 — (⅛)
M. S. with atrop. ¼ gr.	360	318		42 — (¼)
Cod. ¼ gr.	4300	4028		272 — (¼)
Cod. ½ gr.	2100	1874		226 — (½)
	36760	18290	53	18417 (Tab.) 3634 (Gr.)

Dr. Werner's record also showed that between July 8, 1934, and November 14, 1936, he was a voluntary patient on 4 occasions at the Willmar State Hospital. Dr. Werner's hospitalization on those occasions was due to excessive indulgence in alcoholic beverages. Dr. Werner was born on April 4, 1901, at Center City, Minnesota. He was graduated in Medicine from the University of Minnesota in 1926, and was licensed in Minnesota by examination the same year.

Minneapolis Physician's Plea for Pardon Denied

Re: State of Minnesota vs. William M. Chowning, M.D.

On November 29, 1930, the Minnesota State Board of Pardons denied a pardon to Dr. William M. Chowning of Minneapolis. Dr. Chowning was convicted on April 24, 1936, by a jury in the District Court of Hennepin County of the crime of abortion. On November 7, 1936, his license to practice medicine was revoked by the Minnesota State Board of Medical Examiners.

The State Board of Pardons conducted a full hearing in the matter on July 29, 1940, and subsequently thereto. At the hearing before the Pardon Board Mr. L. J. Lauerman of Olivia, Minnesota, representing Dr. Chowning, stated that Dr. Chowning "was framed." Mr. Lauerman, claimed that Dr. Chowning's trouble arose out of his testifying in malpractice suits against members of the American Medical Association and the Minnesota State Medical Association. Dr. Chowning's pardon application was opposed by the Minnesota State Board of Medical Examiners for the reason that the facts in Dr. Chowning's case show that he was indicted by the grand jury of Hennepin County for the crime of abortion and subsequently tried and convicted by a jury in the Court of Judge Montgomery. The records of the Minnesota State Board of Medical Examiners show that Dr. Chowning's license was revoked because of his conviction of a felony, the felony being the crime of abortion.

The members of the Minnesota State Board of Pardons are: Governor Harold E. Stassen, Chief Justice Henry M. Gallagher of the Supreme Court of Minnesota, and Attorney General J. A. A. Burnquist.

LIST OF PHYSICIANS LICENSED BY THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS ON NOVEMBER 8, 1940

October Examination

Aita, John Andrew—U. of Iowa, M.D. 1937, Rochester.

Albers, George Donald—U. of Mich., M.D. 1939, Rochester.

Anderson, Charles Duncan—U. of Western Ont., M.D. 1939, Rochester.

Anderson, Earl Melvin—U. of Minn., M.B. 1940, Minneapolis.

Arling, Philip Arthur—U. of Minn., M.B. 1940, Saint Paul.

Bratholdt, James Wollard—U. of Minn., M.B. 1938; M.D. 1939, Minneapolis.

Brown, Murray Hunter—Yale U., M.D. 1938, Rochester.

Brown, Schuyler Pillsbury—U. of Minn., M.B. 1940, Minneapolis.

Burnham, Wesley Howard—U. of Minn., M.B. 1939; M.D. 1940, Minneapolis.

Carryer, Haddon McCutcheon—Northwestern, M.B. 1938; M.D. 1939, Rochester.

Catinella, Paul Joseph—Tufts Univ., M.D. 1936, Rochester.

Dahlstrom, Doris Elizabeth—U. of Minn., M.B. 1939, Minneapolis.

Davies, Louis Tookey—U. of Neb., M.D. 1939, Rochester.

Ehni, George John—Northwestern, M.B. 1939; M.D. 1940, Rochester.

Fenstermacher, Richard Henry—Jefferson Med. Col., M.D. 1937, Rochester.

Geissler, Gerald George—U. of Minn., M.B. 1939; M.D. 1940, Hinckley.

Glomset, Daniel Anders—U. of Chicago, M.D. 1938, Rochester.

Hallenbeck, George Aaron—Northwestern, M.B. 1939; M.D. 1940, Rochester.

Hartig, Marjorie Eunice—U. of Minn., M.B. 1939; M.D. 1940, Minneapolis.

Higginson, John Francis—Columbia P. & S., M.D. 1937, Rochester.

Honke, Richard Wunnibald—Creighton U., M.D. 1938, Proctor.

Iverson, Rolf Marshall—Northwestern, M.B. 1937; M.D. 1939, Rochester.

Janssen, Martin Ernest—Rush Med. Col., M.D., 1939, Saint Paul.

Judd, David Berkman—U. of Minn., M.B. 1939; M.D. 1940, Rochester.

Kelly, John Francis—U. of Minn., M.B. 1940, Saint Paul.

Leveroos, Edward Herbert—U. of Minn., M.B. 1940; M.D. 1940, Superior, Wis.

Lofsness, Stanley Vincent—U. of Minn., M.B. 1938; M.D. 1939, Minneapolis.

Luckey, Clarence Andrew—U. of Neb., M.D. 1939, Rochester.

Lyman, Richard Watson—U. of Ore., M.D. 1939, Rochester.

Nelson, Clayton Everett Jonas—U. of Minn., M.B. 1940, Saint Paul.

Olson, Stanley William—U. of Ill., M.D. 1939, Rochester.

(Continued on Page 51)

OF GENERAL INTEREST

Dr. and Mrs. Charles E. Rea of Saint Paul announce the birth of a daughter, Mary Virginia, November 20.

* * *

A son, Michael, was born to Dr. and Mrs. William A. O'Brien of Minneapolis, December 1.

* * *

Dr. and Mrs. Francis Lynch are the parents of a daughter, Mary Adeline, born December 11.

* * *

A daughter was born to Dr. and Mrs. Ralph Rossen of Hastings, December 10. She has been named Fredericka.

* * *

Dr. E. A. Thayer of Truman announces the opening of a hospital there. The hospital, a remodeled and modernized residence, has eight beds and three bassinets.

* * *

The marriage of Dr. A. L. Vadheim of Tyler and Mrs. Gladys Donovan took place in Tyler, November 13.

* * *

Dr. George E. Fahr, professor of medicine at the University of Minnesota Medical School, is recuperating after an appendectomy.

* * *

Twin daughters were born to Dr. and Mrs. Alex A. Kugler of Saint Paul, November 27. They have been named Margaret Elizabeth and Patricia Ann.

* * *

Dr. Maud M. Gerdes is now full-time Director of Maternal and Child Health of the Mississippi State Board of Health at Jackson, Mississippi.

* * *

Dedication of a new addition to St. Olaf Hospital in Austin, Minnesota, took place December 1. The 45-bed addition gives Austin a 105-bed hospital.

* * *

Dr. and Mrs. Wallace P. Ritchie of Saint Paul have returned from a month's vacation trip in southern California.

* * *

Dr. R. D. Hanover of Littlefork has taken over the practice of Dr. David M. Potek at International Falls, the latter having been called for active duty in the United States Army.

* * *

Dr. and Mrs. A. E. Benjamin of Minneapolis spent the Christmas holidays in Miami, Florida. They were accompanied by their daughter, Alice, who teaches at Hillsdale School in Cincinnati, Ohio.

* * *

Dr. H. B. Macey and Dr. H. Waltman Walters of Rochester attended a meeting of the Southern Surigcal Association in Hot Springs, Virginia, December 10, 11 and 12.

* * *

Dr. Viktor O. Wilson of the Minnesota State Department of Health will address the Women's Auxiliary of the Minnesota State Dental Association at its annual meeting in February.

* * *

Dr. Arthur C. Skjold is the newly elected president of the Minneapolis Pistol and Revolver Club. Dr. Skjold held the Minnesota civilian pistol championship in 1936.

* * *

Dr. William R. Bagley of Duluth was elected a member of the board of the Minnesota chapter, Izaak Walton League, at its annual convention in Minneapolis which closed December 13.

* * *

Recently elected chiefs of staff of Minneapolis hospitals are: Dr. Duma Carroll Arnold, Asbury Hospital; Dr. Walter Edward Camp, Northwestern Hospital; Dr. Carl Ragnar Wall, Deaconess Hospital.

* * *

Dr. L. A. Nash, who recently completed his fellowship in radiology in the Mayo Foundation at Rochester, is now radiologist at St. John's Hospital in Fargo, North Dakota.

* * *

Drs. M. O. Henry and E. T. Evans of Minneapolis entertained the Minnesota-Dakota Orthopedic Club at a banquet at the Minneapolis Club, December 20, for Dr. Wallace Cole of Saint Paul, who is leaving shortly to take charge of the American Hospital in Britain.

* * *

Dr. Leo G. Rigler, professor of radiology at the University of Minnesota, was toastmaster for the annual banquet of the Twin City Society of X-Ray Technicians, held December 14 at the Curtis Hotel in Minneapolis.

* * *

Dr. M. J. Lindahl has moved into his new hospital-residence in Sherburn. Of colonial style architecture, the building has eleven rooms on the first floor, including living quarters and consultation rooms. It is 77 by 34 feet.

* * *

Among medical courses to be held at the Center for Continuation Study is one in Hospital Administration, January 27 to February 1. Dr. Arthur C. Bachmeyer, director of University Clinics at the University of Chicago, will participate.

* * *

Dr. William B. Castle of Boston, professor of medicine at Harvard Medical School, will participate in the course in Internal Medicine to be given at the Center for Continuation Study on the University of Minnesota campus, March 3-5.

* * *

In Chicago, November 30, for a meeting of the Travel Club of the Central Association of Obstetricians and Gynecologists were Dr. L. M. Randall and Dr. A. B. Hunt of Rochester, and Dr. Claude J. Ehrenberg and Dr. John L. McKelvey of Minneapolis.

Dr. Harold O. Peterson, instructor in radiology at the University of Minnesota Medical School, has entered into practice with Dr. John P. Medelman and Dr. Edward Schons, 572 Lowry Medical Arts Building, Saint Paul.

* * *

Dr. Evelyn Johnson of the Human Serum Laboratory at the University of Minnesota has opened offices in St. Louis Park for the practice of pediatrics. She will continue as clinical instructor in the Department of Pediatrics.

* * *

Dr. C. D. Creevy, assistant dean of the University of Minnesota Medical School, addressed the meeting of the New York Academy of Medicine in New York City, December 18. His subject was "Urinary Calculi Produced by Bacillus Proteus."

* * *

Dr. Charles G. Sutherland of Rochester was elected librarian of the Radiological Society of North America at the organization's meeting in Cleveland. Attending from Minneapolis were Drs. Annette Stenstrom, Leo G. Rigler and C. N. Borman.

* * *

Dr. M. H. Manson, one-time member of the Department of Surgery at the University of Minnesota Medical School and son of Dr. Frank M. Manson of Worthington, became medical director of Bell Telephone Laboratories in New York, November 1.

* * *

Dr. J. Y. Feinstein of Cambridge has opened offices in Grove City, Minnesota. For the past two years, Dr. Feinstein has been senior physician at the State Hospital in Cambridge, and previous to that he practiced at Minot, North Dakota.

* * *

Dr. E. J. Nelson was elected president of the City Hospital staff at Owatonna at a recent meeting. Dr. J. F. Schaefer of Owatonna showed surgical motion pictures prepared by the Northwestern University Medical School.

* * *

Professor R. G. Gustavson, chairman of the Department of Chemistry at the University of Colorado, lectured at the University of Minnesota Medical School, December 12, under the auspices of the Division of Physiological Chemistry. His subject was "The effects of the Synthetic Estrogens Upon the Thyroid Gland."

* * *

Dr. F. Norman Pansch announces the opening of offices for the practice of obstetrics and gynecology in Appleton, Wisconsin. Dr. Pansch interned at Ancker Hospital in Saint Paul in 1936-37, and held a fellowship in obstetrics and gynecology at the Mayo Foundation, 1937-40.

* * *

The University of Minnesota board of regents has accepted a gift of $1,240 from the National Foundation for Infantile Paralysis to be used for a six-months course in orthopedic nursing, beginning with the winter quarter.

Among medical officers of the United States Naval Reserve who are under orders for active duty are:

Lieutenant Frederic F. Wipperman of Minneapolis, to Naval Reserve Air Base, Minneapolis.

Lieutenant Herbert H. Schneider of Rochester, to Naval Hospital, Pensacola, Florida.

* * *

Dr. F. H. Krusen of Rochester represented the Council on Physical Therapy of the American Medical Association at a meeting of the Federal Communication Commission in Washington, D. C., November 29. The meeting was concerned with radio interference by electromedical apparatus.

* * *

Dr. R. H. Beiswanger, physician in Wykoff for eleven years, has disposed of his practice to Dr. Richard Herbst, a recent graduate of the medical school of the University of Minnesota. Dr. Beiswanger with his family has moved to St. Louis Park, and will take a three-year fellowship at the University of Minnesota in roentgenology.

* * *

Dr. Harold S. Diehl, as a member of the Council on Medical Education and Hospitals of the American Medical Association, participated in a survey of the Louisiana State University Medical School in New Orleans recently. Others who took part were Dr. William Cutter of Chicago, secretary of the council, and Dr. Herman Weiskotten, dean of the Syracuse University Medical School.

* * *

Dr. J. A. Williams, who recently completed an internship at St. Mary's Hospital in Duluth, is assistant to Dr. E. K. Rowles at the Rood Hospital in Coleraine. Dr. Williams replaces Dr. A. C. Kelly, who recently took over the practice of Dr. Roy Mayne of Duluth. Dr. Mayne, a medical reserve officer, was called to active duty in the United States Navy.

* * *

Dr. Henry E. Michelson, director of the division of dermatology at the University of Minnesota Medical School, has been invited to give the addresses in dermatology and syphilology at the three-day Post-Graduate Clinics of St. Louis, Missouri, March 11, 12 and 13. The clinics are being sponsored by the St. Louis Medical Society.

* * *

Dr. J. P. Person of Giltner, Nebraska, has become associated in practice with Dr. S. A. Whitson and Dr. Donald Stark Branham in Alden.

Dr. Person began his practice in Alden, November 29, and four days later was elected president of the Civic League at Alden. He succeeds Dr. Whitson, who asked to be retired from the presidency which he has held for a number of years.

* * *

Dr. D. C. Lochead, deputy city health officer at Rochester for sixteen years, has resigned, effective April 14, 1941, and Dr. Floyd M. Feldman, director of rural health of District 3 of the Minnesota State Board of Health with headquarters in Rochester, has been appointed part-time deputy, effective January 1. Dr. Feldman, a graduate of the University of Minne-

LAND LIBRARY Founded 1913 SCHOOL OF MEDICINE

sota Medical School, was formerly associated with the hospital for Indians at Red Lake.

* * *

Sponsored by the Hennepin County Medical Society and the Minneapolis Surgical Society, the second annual fracture symposium will be presented at the Minneapolis General Hospital and the Society Auditorium, January 6.

Dr. Fraser Baillie Gurd, surgeon with the Canadian Expeditionary Force in the first World War and attending surgeon at the Montreal General Hospital, will be the principal speaker. His subject will be "Treatment of Gunshot Wounds."

* * *

Dr. Karl H. Pfuetze, who has been assistant to Dr. W. D. Beadie at the Mineral Springs Sanatorium for the past few months, has been appointed superintendent of the Sanatorium to succeed Dr. Beadie who recently resigned because of ill health.

Dr. Pfuetze's appointment was effective December 4. Before coming to Mineral Springs, Dr. Pfuetze was assistant at the Nopeming Sanatorium.

Dr. and Mrs. Beadie have gone to Windom to make their home.

* * *

Attending the meeting of the American Academy of Dermatology and Syphilology in Chicago, December 8-11, were Drs. P. A. O'Leary, L. A. Brunsting and Hamilton Montgomery of Rochester, and Drs. H. E. Michelson and L. H. Winer of Minneapolis.

Dr. Montgomery was chairman of the dermatopathology roundtable. Dr. Michelson, as a member of the American Board of Dermatology and Syphilology, spent the week prior to the session assisting in examination of candidates.

* * *

The Minnesota Society for the Control of Cancer filed articles of incorporation, December 12.

Dr. William A. O'Brien of Saint Paul is president of the society; Dr. Max W. Alberts of Saint Paul, vice president; Mrs. S. L. Carr of Minneapolis, secretary; Louis W. Hill, Jr., of Saint Paul, treasurer.

Other members of the board are Dr. Charles W. Mayo of Rochester; Dr. Guy Stanton Ford, president of the University of Minnesota; Mrs. Howard Overman of Saint Paul and Mrs. Harlow Hanson of Minneapolis.

* * *

Dr. Russell M. Wilder of Rochester has been named chairman of a national committee to study nutritional aspects of national defense. This new committee on food and nutrition was set up by the National Research Council.

In accepting the chairmanship, Dr. Wilder relinquished the chairmanship of the committee on medicine and the subcommittee on nutrition to which he was appointed last summer.

Dr. Wilder attended an organization meeting of the new committee in Washington, D. C., early in December.

Organization of a general hospital unit for service in any theater of operations in the event of war is being sponsored by the Mayo Clinic and the Mayo Foundation. The unit will be known as the 71st General Hospital Unit. It is one of 102 units authorized by the war department, and is the second to be organized in the state, the University of Minnesota sponsoring the other unit. In the first World War, the Mayo Clinic and the Mayo Foundation coöperated with the University of Minnesota Medical School in the organizing of Base Hospital 26.

* * *

Inoculation of 800 University of Minnesota students with a newly developed influenza vaccine was begun December 11, in an effort to test effectiveness of the serum if an epidemic now on the West Coast spreads to Minneapolis.

A limited supply of the vaccine was obtained from the Minnesota State Board of Health which is cooperating with the Rockefeller Institute for Medical Research in testing the vaccine. Similar tests are also being carried on in other cities.

Inoculations were begun in December, according to Dr. Donald Cowan who is assistant to Dr. Ruth Boynton, director of the Student Health Service, because it has not been determined how soon the vaccine becomes effective, and because it can be tested only during an epidemic.

* * *

Enlargement of the field of scientific research was urged by Dr. Guy Stanton Ford, president of the University of Minnesota, in his biennial message to the board of regents, December 13. The report was the last he will deliver, for he retires in June after twenty-eight years in leading administrative posts on the campus.

Pointing out that American industry invests $300,000,000 annually in medical research alone, Dr. Ford urged support of research in the university.

"With all appreciation of the friendly understanding of the last legislature," he said, "I have never been able to follow why the modest and inadequate sum granted for research in our medical school was reduced.

"The $5,00 thus saved, if 'saved' is the word to use, would have enabled a specially competent group to make a beginning on a perhaps long-time campaign against such heart-rending disease as epilepsy, or on other diseases from which we now only pray that chance will deliver us and our children.

"When similar diseases invade our fields or our herds, we bestir ourselves mightily."

* * *

A portrait of Dr. Jennings C. Litzenberg of Minneapolis, University of Minnesota professor emeritus and for many years head of the obstetrics and gynecology department at the University Medical School, was unveiled at a dinner at the Minneapolis Club, December 19, and was presented to Dr. Guy Stanton Ford, president, who received the gift for the University. The portrait was painted by Edward Brewer of Saint Paul.

Guests included a group of men who received their

Ph.D. degrees at the University under Dr. Litzenberg: Drs. Roy E. Swanson, S. B. Solhaug, L. A. Lang, M. Abramson, E. C. Maeder of Minneapolis and Drs. L. W. Barry and E. M. Kasper of Saint Paul.

Department heads of the Medical School who were among the guests were: Dr. Harold S. Diehl, dean of medical sciences; Dr. J. L. McKelvey, head of obstetrics and gynecology; Dr. Frank Burch, ophthalmology and otolaryngology; Dr. Irvine McQuarrie, pediatrics; Dr. Owen Wangensteen, surgery.

Fred B. Snyder represented the board of regents. Other guests include Dr. Robert Mussey of Rochester, and Dr. Russell Morse, president of the Hennepin County Medical Association.

* * *

In addition to those listed in the December issue of MINNESOTA MEDICINE the following medical reserve officers in the United States Army have been called to active duty:

Dr. John H. Grindlay of Rochester, first lieutenant, to Randolph Field, Texas.
Dr. F. P. Arny of Preston.
Dr. J. A. Mason of International Falls, first lieutenant, assigned to Camp Joseph T. Robinson at Little Rock, Arkansas.
Dr. John Johnson of Kerkhoven.
Dr. D. M. Potek of International Falls, first lieutenant.
Dr. C. G. Wingquist of Crosby, captain.
Dr. Luverne J. Webster of Battle Lake, head of Otter Tail County Sanatorium, assigned to Camp Joseph T. Robinson at Little Rock, Arkansas.
Dr. Leo Francis Bach of Mapleton, captain.
Dr. Edward Bruce Badger of Minneapolis, captain.
Dr. Robert Jacob Brotchner of Saint Paul, first lieutenant.
Dr. Albert Sinai Brussell of Saint Paul, captain.
Dr. Henry B. Clark, Jr., of Saint Paul, captain, assigned to Camp Joseph T. Robinson.
Dr. Maurice F. Ekstrom of Saint Paul, first lieutenant, assigned to Camp Joseph T. Robinson.
Dr. Harry Samuel Friedman of Minneapolis, first lieutenant.
Dr. William C. Hartland of Crosby, captain.
Dr. Jack Hartman of Minneapolis, first lieutenant.
Dr. Paul Kisner of Fort Snelling, captain.
Dr. Carl John Lind, Jr., of Minneapolis, captain.
Dr. Joseph Francis Melancon of Saint Paul, first lieutenant.
Dr. Joseph C. Olson, Jr., of Saint Paul, first lieutenant, assigned to Camp Joseph T. Robinson.
Dr. Sidney S. Scherling of Taylor Falls, captain, assigned to Camp Joseph T. Robinson.
Dr. James M. Brown of Caledonia, first lieutenant, assigned to Camp Joseph T. Robinson.
Dr. Wayne S. Hagen of Minneapolis, captain, assigned to Camp Grant, Illinois.

* * *

A large number of Minnesota men were in attendance at the fiftieth anniversary meeting of the Western Surgical Association, which was held December 6 and 7 in Topeka, Kansas, the city in which the association was founded.

The Association voted to hold its 1941 meeting in Saint Paul next December.

Among those who participated in the program at the Topeka session were Dr. S. W. Harrington and Dr. H. Waltman Walters of Rochester. The latter's subject was "Malignant Lesions of the Stomach; Results of Treatment from 1907 through 1938."

Dr. Harry B. Zimmerman of Saint Paul was elected recorder.

Among those elected to membership in the Association were Dr. Wallace P. Ritchie of Saint Paul, and Dr. J. T. Priestley of Rochester.

Attending the meeting besides Drs. Harrington, Walters and Zimmerman, were: Drs. Harry P. Ritchie, Robert Earl, E. Mendelssohn Jones, and N. Logan Leven of Saint Paul; Drs. A. E. Benjamin, William T. Peyton, Arthur C. Strachauer, O. J. Campbell, Martin Nordland, Roscoe C. Webb, S. R. Maxeiner and T. J. Kinsella of Minneapolis; Drs. William Dean Coventry and A. L. McDonald of Duluth; and Drs. A. W. Adson, C. F. Dixon, V. S. Counseller, and W. McK. Craig of Rochester.

LIST OF PHYSICIANS LICENSED

(Continued from Page 47)

Pender, John William—Tulane U., M.D. 1935, Rochester.

Petit, Julian Victor—U. of Minn., M.B. 1940, Minneapolis.

Petkevich, Frank Michael—U. of Chicago, M.D. 1937, Minneapolis.

Pleissner, Karl William—U. of Minn., M.B. 1940, Minneapolis.

Ponterio, James Edmund—Creighton U., M.D. 1940, Saint Paul.

Potter, Robert Tippett—U. of Minn., M.B. 1939, Minneapolis.

Pratt, Joseph Hyde, Jr.—Harvard U., M.D. 1937, Rochester.

Pruitt, Raymond Donald—U. of Kansas, M.D. 1939, Rochester.

Rogers, George Edward Brien—U. of Toronto, M.D. 1938, Minneapolis.

Rushmer, Robert Frazer—Rush Med. Col., M.D. 1939, Rochester.

Schulze, William Matthew—U. of Minn., M.B. 1939; M.D. 1940, Minneapolis.

Schwyzer, Arnold Gustav—Johns Hopkins U., M.D. 1939, Saint Paul.

Sluder, Fletcher Sumpter, Jr.—Rush Med. Col., M.D. 1938, Rochester.

Smith, Frank Baker—McGill Univ., M.D. 1937, Rochester.

Strough, LaVern Craig—U. of Neb., M.D. 1939, Minneapolis.

Sutton, Janet Beth—U. of Minn., M.B. 1939, Minneapolis.

Wise, Ralph Waldo Emerson—U. of Iowa, M.D. 1939, Rochester.

By Reciprocity

Blum, Otto Schidler—U. of Wis., M.D. 1929, La Crosse, Wis.

Chesley, Ward Bennett—U. of Mich., M.D. 1937, Virginia.

Galloway, John D. Brown—Temple U., M.D. 1934, Minneapolis.

Hausmann, Paul Frederic—Northwestern, M.B. 1938; M.D. 1939, Rochester.

Mulmed, Earl I.—U. of Okla., M.D. 1937, Rochester.

Nielsen, Ariel Elias—U. of Louisville, M.D. 1936, Douglas, Wyo.

Noble, Philip Cornelius—Rush Med. Co., M.D. 1929, Minneapolis.

Patch, Orien Bailey—Western Reserve, M.D. 1935, Duluth.

Person, John Paul—U. of Neb., M.D. 1934, Alden.

Rosenbaum, Edward E.—U. of Neb., M.D. 1938, Rochester.

Rosenberg, Charles Freelan—U. of Wis., M.D. 1936, Madison, Wis.

Zeman, Edward William—U. of Neb., M.D. 1936, Omaha, Neb.

National Board Credentials

Boyd, Edith—Johns Hopkins, M.D. 1921, Minneapolis.

Flannary, Hubert Farber—Rush Med. Col., M.D. 1939, Saint Cloud.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR JANUARY

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Professor of Preventive Medicine and Public Health, Medical School, University of Minnesota.

The program for the month will be as follows:

January 4—Common Cold.
January 11—Influenza.
January 18—Pneumonia.
January 25—Exodontia.

ANNUAL FORUM ON ALLERGY

The third annual Forum on Allergy will take place Saturday and Sunday, January 11 and 12, 1941, at Indianapolis, Indiana. The intensive program condensed to fill one week-end is the result of suggestions on the part of those who attended the last meeting in Chicago in January, 1940. Of the physicians who attended last year's meeting 146 have signed up for this year's week-end. Both clinicians and those in attendance come from every part of the country. The topics to be discussed will be of interest to internists, pediatricians, dermatologists, otolaryngologists, and all engaged in the practice of medicine.

Registrations should be mailed in advance to Dr. Toll Nelson, 636 Church Street, Evanston, Illinois.

E. STARR JUDD LECTURE

The eighth annual E. Starr Judd lecture at the University of Minnesota will be delivered by Dr. Andrew C. Ivy, professor of physiology and pharmacology at Northwestern University Medical School, January 15. His subject will be "The Mechanism of Gastric Secretion."

MINNESOTA PATHOLOGICAL SOCIETY

Dr. W. M. Stanley of the Rockefeller Institute for Medical Research, Department of Animal and Plant Pathology, Princeton, New Jersey, will address members of the Minnesota Pathological Society, January 21. He will speak on "Some Chemical, Medical and Philosophical Aspects of Viruses."

PHYSICAL THERAPY COURSE FOR TECHNICIANS

The Medical School of the University of Minnesota will inaugurate a course for the training of technicians in Physical Therapy beginning with the Summer Session of 1941. This is a twelve-month course open to graduate nurses, graduates in physical education and graduate medical technicians. The curriculum will cover the entire field of Physical Therapy with abundant clinical training in affiliated hospitals.

Since there is a shortage of well-trained physical therapy technicians in the United States, this course offers excellent training in a field which is rapidly developing and is still full of opportunities. It is believed that in the event of war the army hospitals will require more technicians than are registered in the entire country at the present time.

MINNESOTA STATE SANITARY CONFERENCE

Dr. D. C. Lochead of Rochester was elected president of the Minnesota State Sanitary Conference at a meeting in Minneapolis, November 29. Dr. A. J. Chesley of Saint Paul was reëlected secretary-treasurer, and Dr. C. N. Harris of Hibbing was named vice president. New directors elected to serve until 1943 are Dr. A. T. Laird, of Nopeming, Dr. G. H. Luedtke of Fairmont and Dr. J. P. Wilkins of Mound.

Dr. J. Lawrence McLeod of Grand Rapids is a new member of the Legislative Committee.

Physicians on the conference program included: Dr. T. B. Magath, Rochester health officer and vice president of the state board of health; Dr. O. O. Larsen of Detroit Lakes, who served as president of the conference during the past year; Drs. L. W. Foker and L. S. Arling, State Medical Association Committee; Dr. F. M. Feldman of Rural Health District 3; Dr. J. F. Worley, U.S.P.H.S., director of the Indian Medical Service; Dr. R. R. Sullivan and Dr. Hilbert Mark of the Minnesota State Department of Health; Dr. H. S. Diehl of the University of Minnesota; Dr. L. L. Sogge, chairman of the Public Policy Committee of the State Medical Association; Dr. A. T. Laird, superintendent of Nopeming Sanatorium; Dr. L. J. Webster, superintendent of the Otter Tail County Sanatorium; Colonel Kent Nelson, M.C., United States Army.

RICE COUNTY MEDICAL SOCIETY

Dr. C. Dexter Lufkin of Northfield was elected president of the Rice County Medical Society at the annual meeting in Faribault recently. Other officers elected are Dr. Carl A. Traeger of Faribault, vice president, and Dr. Paul Weaver of Faribault, secretary-treasurer.

NICOLLET-LE SUEUR MEDICAL SOCIETY

Dr. J. F. Traxler of Henderson was elected president of the Nicollet-LeSueur Medical Society at the organization's annual meeting in St. Peter. He succeeds Dr. Burton Grimes of St. Peter.

Dr. A. S. Nissen of St. Peter was elected vice president, and Dr. C. S. Strathern of St. Peter, secretary-treasurer. Dr. Nissen was named delegate to the state medical convention, and Dr. Swan Ericson of Le Sueur, alternate.

Guest speaker at the meeting was Dr. Owen Robbins of Minneapolis.

GEORGE CHASE CHRISTIAN LECTURE

Dr. F. Peyton Rous of the Rockefeller Institute for Medical Research, New York City, will deliver the annual George Chase Christian lecture at the University of Minnesota early in February.

The title of his lecture, which will be concerned with a phase of cancer research, has not yet been announced.

SIOUX VALLEY MEDICAL ASSOCIATION

Dr. E. A. Kilbride of Worthington, Minnesota, is the newly elected president of the Sioux Valley Medical Association, composed of physicians from South Dakota, Iowa, Minnesota and Nebraska.

He was elected at the closing session of a two-day convention held in Sioux Falls, South Dakota, December 4 and 5. Sioux City was chosen as the 1941 meeting place.

Other officers named were Dr. R. S. Westaby of Madison, South Dakota, vice president; Dr. Roy E. Crowder of Sioux City, secretary; and Dr. F. P. Winkler of Sibley, Iowa, treasurer.

AMERICAN COLLEGE OF SURGEONS SECTIONAL MEETING

A sectional meeting of the American College of Surgeons will be held in Minneapolis, March 10, 11 and 12.

More than a thousand surgeons from eight states and one Canadian province are expected to attend. Participating will be surgeons from Minnesota, North Dakota, South Dakota, Iowa, Nebraska, Wisconsin, Kansas, Montana and Manitoba.

In addition to Fellows of the College, members of the medical profession at large, and persons interested in the institutional care of the sick and injured, are invited to attend. The general public is invited to a meeting on Health Conservation to be held the evening of March 12, in Northrop Memorial Auditorium on the University campus.

The program will include the presentation of all types of surgery in hospitals and clinics, papers and panel discussion. More than a score of national figures in surgery will appear as guest speakers. In addition, an elaborate scientific exhibit will feature the meeting.

Dr. William A. Hanson has been named chairman of the Minneapolis committees on arrangements. Dr. William E. Patterson and Dr. Myron O. Henry will serve as vice chairmen, and Dr. James M. Hayes, as secretary.

Chairmen of sub-committees are Dr. L. Haynes Fowler, clinics; Dr. Frederick A. Olson, exhibits; Dr. Thomas J. Kinsella, meeting on health conservation; Dr. James A. Johnson, program; Dr. Martin Nordland, public relations and speakers' assignments; Dr. Theodore H. Sweetser, reception and entertainment; Dr. Arthur F. Bratrud, motion pictures; and Dr. Henry E. Hoffert, transportation and hotels.

Mrs. James A. Johnson is chairman of the committee on ladies' entertainment. She is being assisted by Mrs. Russell W. Morse, vice chairman.

SIGMA XI LECTURES

The University of Minnesota chapter of Sigma Xi, national honor society in science, is again sponsoring a series of science lectures for the general public.

The lectures will be presented in Northrop Memorial Auditorium at 8:15 p. m. on four Fridays in January and February. There is no admission charge.

Opening the series will be Dr. Lloyd H. Reyerson, who will lecture on "Chemistry and Our National Defense," January 31. Dr. Reyerson is professor and administrative assistant in chemistry.

On February 7, Dr. Maurice B. Visscher, head of the division of general physiology in the Medical School, will speak on "Your Heart and You."

"The Common Cold" will be the title of the lecture to be given by Dr. Harold S. Diehl, dean of medical sciences, February 14.

The concluding lecture of the series will be given February 21 by Dr. William A. O'Brien, director of post-graduate medical education. His subject will be "Meeting Middle Age."

CORRESPONDENCE

MANTOUX TESTS IN ALBERT LEA HIGH SCHOOLS

During 1939, the Freeborn County Medical Society performed the Mantoux test on 985 students in the Junior and Senior High School of the Albert Lea schools. Of this entire group 72 (7.2+ %) were found positive. Within this group were thirty-four pupils from the rural area, who had driven with a school bus driver having an active case of pulmonary tuberculosis. Of these, fifteen (44+ per cent) were found to react positively. This bus driver, formerly a farmer, found that farm work brought on fatigue, so he sought and obtained his rest cure as a school bus driver. There was no one to say him nay. He continued driving and coughing (and here we quote from patrons of the school) "until he became so weak he could not turn the bus around alone. Then he quit."

It seems that such tragedies could be largely prevented, if regulations were made and enforced in all schools, that before any contracts are given, all prospective employees of a school must present a certificate that they are free from active tuberculosis, as revealed by the best known methods at our command—the Mantoux test, x-ray and physical examination.

L. J. Kaasa, M.D.

NOTICE

To whom it may concern:

The undersigned, Daniel H. Bessesen, M.D., formerly vice president of the College of Commerce, Inc., has resigned and relinquished his association with said corporation, as of the date, November 16, 1940, and any further use of my name since that date, in connection with the business or affairs of the College of Commerce, Inc., is unauthorized.

(Signed) Daniel H. Bessesen.

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

Meeting of October 9, 1940

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 9, 1940. Dinner was served at seven o'clock and the meeting was called to order at 8 p.m. by the President, Dr. James Johnson.

There were fifty-six members and three guests present.

Minutes of the May meeting were read and approved.

Dr. S. E. Sweitzer read the following Memorial to Dr. Frank R. Wright, and a motion was carried that this be spread on the minutes of the Academy and a copy sent to the family.

FRANKLIN R. WRIGHT

1866-1940

Dr. Franklin Randolph Wright, prominent Minneapolis urologist, died August 1, 1940, at the age of 74 years.

Dr. Wright had been a member of the university faculty for 41 years at the time of his retirement in June, 1936, with the rank of Associate Professor Emeritus of Urology. The American Urological Association and the Twin City Urological Society, of which he had long been an influential member, honored him in May of this year through the establishment of the Franklin R. Wright lectureship at the university.

A pioneer in the urological field, Dr. Wright gave their training in venereal disease control to most of the doctors graduated at Minnesota since the turn of the century.

He was born in Canton, Illinois, the son of a physician, Colonel George W. Wright. Following his graduation from the Shenandoah, Iowa, high school, he entered the dental school of the Minnesota Hospital College in 1887, and was graduated in 1890 after the institution had become the dental department of the university.

After two years of dental practice in Hutchinson, Minnesota, Dr. Wright returned to the university to study medicine and received his M.D. degree in 1894. After his internship in Asbury and St. Barnabas hospitals, Dr .Wright did dermatology and venereal disease work with Dr. Max Vander Horck. He was appointed to the university faculty in 1895. Three times—in 1900, 1902 and 1906—Dr. Wright went abroad to take postgraduate work in Berlin and Vienna. During the World War he had charge of the urological work at Camp Custer.

Dr. Wright was made a Fellow of the American College of Surgeons in the 1913 class—the first class chosen by the group's founders. He also was a member of the American Urological Association, the Twin City Urological Society, the Minnesota Dermatological Society, the Chicago Urological Society, the American Medical Association, the Minnesota Academy of Medicine, the Minnesota State Medical Association and the Hennepin County Medical Society.

He also was a member of the Minneapolis Club, the Masonic order and Nu Sigma Nu medical fraternity, and was on the staffs of University, St. Andrews, St. Barnabas, and Eitel hospitals. He retired from active practice recently.

With the death of Dr. Franklin R. Wright, Minnesota has lost one of its outstanding medical men. He loved to teach and did teach for many years at the University of Minnesota. Any young medical man could ask advice from him and it would be freely given. He had a marvelous memory and enjoyed discussing papers, which he did in an inimitable way. His remarks were pungent and he always said what he really thought and was usually right.

The writer went with him to the meetings of the Minnesota Academy of Medicine in Saint Paul for many years. Driving him over from Minneapolis, we talked of many things from "cabbages to kings." He was an interesting personality and a loyal friend.

He will be missed and has left an honorable record of achievements in medicine in Minnesota. —S. E. S.

The scientific program followed.

IDIOPATHIC ULCERATIVE COLITIS

Arnold Schwyzer, M.D.
Saint Paul, Minnesota

To bring this subject for discussion notwithstanding the very small personal experience to which I must confess from the start, has a twofold cause. First of all, the views as to the proper treatment, medical as well as surgical, still differ considerably; and second, my personally observed cases may have some points of interest.

It is not the intention to go into a general discussion of the disease and its treatment beyond a few remarks. One is impressed by the divergent views regarding the treatment when one studies Bargen's work based on the enormous material of the Mayo Clinic and then goes through a paper on the subject read by McKittrick before the American Surgical Association in 1935. The discussion following that paper is of particular interest to the surgeon. Just what is best to do when surgical relief becomes imperative cannot be stated categorically. We are here confronted by a problem where surgery to bring relief in one direction creates often an almost intolerable condition in other ways.

Bargen of the Mayo Clinic appears to have had more experience with medical treatment than perhaps anybody else. In 1933 he reports on a ten years' experience with 1,348 cases[1] He isolated a diplostreptococcus which he considers specific not for all, but for the great majority of these cases. He studied the lesions microscopically and found thrombotic conditions not only in the mucosa but also in the deeper

walls of the gut. Thus one of the characteristics of the disease becomes readily comprehensible, namely the great thickening of the gut wall and the cicatricial foreshortening of the colon tube with loss of haustration. In order to designate this overwhelmingly large group due to a specific agent among the generally named idiopathic form he calls it "thrombo-ulcerative" or also "diplostreptococcic ulcerative" colitis. The bacteriologic findings were apparently not in harmony with the studies at the Massachusetts General Hospital; but when Bargen reports out of 1,348 patients 898 as symptom-free, plus 82 as greatly improved, one cannot help being impressed. About 10 per cent are reported as having died and about 8 per cent as unimproved. These patients were treated with a specific anti-diplostreptococcic serum followed by vaccine injections every five days for months. If possible this vaccine was to be autogenous.

McKittrick does not discuss other treatment than the surgical after medical had proven to be helpless or inadequate[4] As the few cases I am to report were judged to require prompt surgical relief except one, I am not going to discuss the medical treatment and will now simply report on our surgical management.

Case Reports

Case 1.—Mrs. F. P., thirty-three years old, came to us in February, 1919, with a history of having suffered from pain and diarrhea for five years. The bowels moved five to six times a day, and she had much abdominal pain. There were no amebæ found. By different measures she was more or less improved, but returned very discouraged and miserable in February, 1920, after having had frequent spells of great pain. An appendicostomy was made on February 25, 1920, followed by irrigations of the colon, first twice a week and later once. Her best weight ever had been 130 pounds. At the time of operation it was 107 pounds. Four months later it had gone up to 115. She looked very well and felt better. The catheter in the appendicostomy was then removed. After a while the old symptoms recurred alternating with times of some improvement. We did not see her again until February, 1926. There had been no change. The colon from the splenic flexure down showed no haustra, but was not markedly narrowed. Proctoscopically the mucosa was generally congested. She did not appear to be bad enough for surgical interference nor would she have any. We have not seen her since then. On inquiry in February, 1940, she wrote that her condition of late was very bad though she had been doctoring for all these years. A course of Bargen's treatment or with neoprontosil or possibly a colostomy would be advisable.

This is a case which might well have been greatly benefited by Bargen's serum and vaccine, had we had it in those early days. Lockhart-Mummery had considered appendicostomy "the best treatment" for ulcerative colitis.

Case 2.—Miss I. C., eighteen years old, came to us in 1922 with an intractable hemorrhagic colitis from which she had suffered for several weeks. On March 4, 1922, an appendicostomy was made, which was used for irrigations of the colon. These irrigations were done first twice weekly and later only once. She improved gradually though not steadily as there were intervals of bloody diarrhea during the first months. By January, 1923, the appendicostomy was allowed to close. She felt well and was married that same month. In 1926 she had a baby and for one month after that she noticed some blood in the stools; however, there was no pain. She was then not seen till October, 1929, when a painful hernia had developed at the site of the appendicostomy. The bowels apparently did not bother her much. When constipated she noticed a little blood, but gave it no further attention. The hernia was repaired and the stump of the appendix resected. Six weeks after this operation the last entry on her chart reads: "Pain around the navel (which had brought her back to Saint Paul with the mentioned hernia condition) is gone since the operation. Bowels need a little mineral oil every evening."

On February 22, 1940, we received upon inquiry the report that she had been "perfectly" well for sixteen years after that operation until two years ago. Her bowels had moved usually once a day and were entirely normal. She used to take some petrolagar. However, two years ago blood and pus appeared again. Her doctor declared it again ulcerative colitis after proctoscopic examination. For a whole year she was in bed and suffered very much. For three months she received daily acriflavin injections, then enemas with oil, etc., etc. At the end of that year she was taken to Rochester where Dr. Bargen treated her with serum and vaccine and neoprontosil. Within three weeks she felt well enough to go home and though she was advised to return later on, never went back as she felt completely well ever since. She thinks that cod liver oil which Dr. Bargen had ordered did her very much good. Her present weight is 160 pounds though she is only five feet and two inches tall. The bowels move from two to five times a day. Some mucus is present, but she feels and looks well. It is interesting that she was apparently very sensitive toward the serum of which she received about ten very small injections. The case is of particular interest inasmuch as some prominent men have expressed very little faith in such treatment. Another feature of interest is the demonstration that ulcerative colitis may recur after years of clinical "cure." I have little doubt that Bargen's treatment would have cured this patient at the first attack when I had charge of the patient, if the serum had been available at that time.

Case 3.—A girl, R. D., fourteen years old, was brought to us on March 7, 1930, with a history of a colitis from which the child had suffered for ten years. Her mother told us that the child had been strong for the first two years. She then seemed to do reasonably well up to the age of seven or eight years except for continuously loose stools. For the last four years, *i.e.,* from the age of ten to fourteen years, she had not grown any. She had been at the Mayo Clinic several times where at no time was any parasitic infection found. She had lived in Montana all her life. Her mother told us that a year ago multiple ulcers had been noticed in the colon. She had almost continuously blood in her stools for the last four years, and much mucus. The bowels were moving six to eight times daily. The last few years the feces had a very offensive odor. The hemoglobin had been down to 34 per cent in October, 1929, and she then had two transfusions.

Physical findings: Temperature 99.8, pulse 114. The examination of the different organs yielded nothing of interest except a painful, tender, and somewhat distended abdomen. According to the general appearance the apparent age instead of fourteen years was more readily judged to be eight years. The drawn colorless face resembled that of an old woman. She seemed to be in constant misery. The stools contained some blood and considerable pus.

On March 10, 1930, an x-ray study at St. Joseph's Hospital after an opaque enema showed most of the colon well filled. Barium had entered the lower ileum. Haustral markings were absent throughout.

On March 14, we made an ileostomy through a grid-iron incision at McBurney's point. The first intestine presenting was the sigmoid flexure which was very fleshy and rigid; its fatty fringes were hard and rounded. The cecum was found fixed toward the posterior abdominal wall and could not be brought into the wound, because when the intestines were grasped subserous bleeding occurred readily. The lowest ileum loop was also fleshy, thickened and somewhat rigid for about seven centimeters from the cecum. A little beyond this area we made the stoma. Only a cherry-size portion of the gut was allowed to protrude from the circular intestino-cutaneous suture.

The relief after opening the ileostomy was very gratifying. The patient left the hospital on April 9, after having gained five pounds since the operation. She was still very anemic.

At the time of the operation the girl had weighed fifty-one pounds. Three months later her mother writes that the weight was seventy-one pounds and that the patient was gaining every day.

Six months after the ileostomy (September, 1930) she returned to us looking very well, but some eversion of the gut had occurred. Mother and daughter urged us intensively to close the ileostomy because she felt so well and was greatly annoyed by this additional opening. Mother and daughter were quite willing to accept all responsibility for the procedure. It seemed impossible to put them off, and on September 29 we closed the ileostomy which after all was a minor procedure, and if necessary could be undone readily. The gut was only partly freed, and the peritoneal cavity was not opened. The mucosa was simply separated from the skin and then the intestinal wall inverted with two superposed linen purse-string sutures. Two fine linen mattress sutures approximated the fascia. We expressed the possibility and even probability of having to re-open the ileostomy. A year later, September 28, 1931, the notes read that she had grown 2.5 to 3 inches since the closing of the ileostomy, in all about 4 inches since the ileostomy a year and a half before. She had felt "fine" up to July, but with the advent of hot weather, she was "not quite as well." The bowels became "terribly" loose again. A small fecal fistula had persisted; there was, however, only very little fecal discharge. The bowels had then become somewhat better, moving about four times in twenty-four hours. This improvement seemed to be due to paracotoin given by mouth. The fistulous tract became gradually almost insignificant so that it did not seem advisable to do much of an operation. However, minor attempts like hot wire cauterization and resuturing having been unsuccessful, a free opening of the peritoneal cavity would be necessary for a complete closure. So far we have held back. The patient has developed into a stately young woman, has grown much in height, and when last seen in October, 1938, was of good normal weight.

Fig. 1. Case 3. Radiograph taken October, 1938. Barium enema shows loss of haustra, but rather good filling eight years after closing of ileostomy.

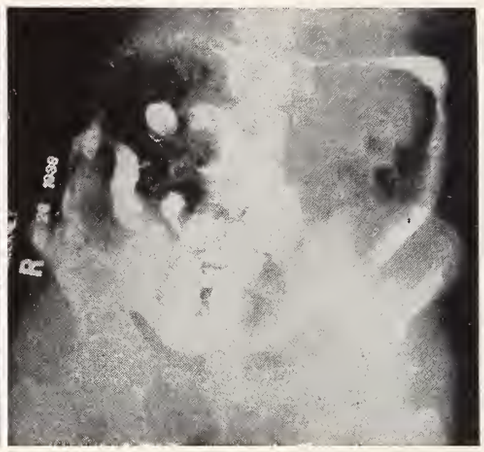

Fig. 2. Case 3. After partial expulsion of barium enema, polyps are seen in descending colon.

Roentgenologic examination was last made in October, 1938. There was evidence of polyposis and the walls of the colon were seen to be very thick. The patient is therefore far from being cured though her general appearance was excellent when we last saw her. It must be taken into consideration that she had been a very severe case and that other measures had been fruitless. For four years she had been treated at intervals at the Mayo Clinic. She had gone through two series of serum treatment followed each time by vaccine injections every five days for six months.

The Rochester Clinic very kindly let us see the roentgenograms made in 1925, 1927, and 1929. Already in July, 1925, the pictures show the lack of haustra and a reflux into the ileum. The colon is quite narrow and shortened. In the 1929 pictures the outline of the barium shadow is fuzzy. A roentgen film made on October 28, 1938, nine years and eight months after the ileostomy shows nothing to be proud of, but the barium shadow gives measurements which appear at least not to have become worse in the eight years since the ileostomy was closed. These measurements are about the same as in 1927 and rather better than in 1929. As mentioned, the shadow of the walls of the colon is seen to be quite thick in the 1938 pictures. They measure mostly about 3/16 of an inch, part of which may, however, be accounted for by the contraction of the emptied gut. After partial emptying of the enema some small polyps are well recognizable in the descending colon (Fig. 2).

Upon our inquiry the young lady writes on February 12, 1940: "My general health is very good. I weigh 113½ pounds, and I am 5 feet ½ inch tall. My hemoglobin is 80 per cent (Sahli). I believe this is better than it has ever been. I do have cramps quite frequently. My bowels move on an average of about seven times in twenty-four hours. I also have a little pain at times. My side drains very little now. I change the dressing about once every two days. It sometimes gets a little irritated, but otherwise does not bother me a lot. My appetite is good and my strength and vitality are very good." It seemed proper to give this report in full as I have not run across case reports where an ileostomy was closed secondarily and was followed by a liveable condition ten years after the ileostomy. The contrast between this favorable report

and the x-ray pictures which demonstrate a far-advanced condition is surprising and noteworthy.*

Case 4.—Mrs. H. C., thirty-five years old, was first admitted to St. Joseph's Hospital under Dr. J. N. Dunn's care on April 1, 1931, for a severe diarrhea which had started acutely a month previously and was getting worse. She had had lighter spells like this several times since 1927. This time the patient had noticed a great deal of mucus and blood from the start of the attack. Of late there were ten to twelve stools every twenty-four hours. Bacteriologic examination of the stools were negative for dysentery, typhoid or paratyphoid bacilli; nor were amebæ found at any time. Much pus and some red cells were seen. The white cell count was 17,200 on April 1, 1931, and 20,100 on April 10. The hemoglobin was 77 per cent. Examination revealed nothing further of interest except a moderate tenderness of the abdomen. Proctoscopic examination (Dr. Dunn) showed the rectal mucosa far up intensely reddened, covered with a purulent discharge and blood. She was treated with different medicaments and irrigations. On April 25 she was allowed to go home, being improved. In October, 1931, she reëntered the hospital and was kindly given into our service. X-ray examination showed the large gut from the left side portion of the transverse colon downward to be narrowed to a ribbon-like tube. The cecum, ascending colon, and proximal part of the transverse colon appeared normal.

Since March she had lost 40 pounds and had had diarrhea alternating with constipation, at which latter periods she suffered from severe bearing-down pains. A stricture of the rectum had been stretched several times.

On October 19, 1931, an ileostomy was then done through a muscle splitting incision at McBurney's point. On November 1 our patient was discharged. She returned for control November 28 feeling "grand" as she expressed it. On October 27, her weight had been 78 pounds. She gradually gained very much in weight and looked not only well but was actually quite plump, apparently heavier than she ever had been. She had gone through so much torture before the ileostomy that she put up with the ileostomy for a long time, but after two years and four months she wanted the artificial anus closed.

Fig. 3. Case 4. Radiograph taken April 8, 1932, six months after ileostomy. The general condition was very much improved.

Fig. 4. Case 4. Radiograph taken October 25, 1933. Notwithstanding the splendid general improvement, the shrinking has progressed when compared with Figure 3, taken a year and a half previously. Note the great thickening of the walls of the colon.

Fig. 5. Case 4. Sketch of ileoproctostomy. Ileum drawn into vagina and one-half of Murphy button (*B*) inserted. The other half is in the infraperitoneal part of the rectum.

This case represented a very vicious and rapidly progressing destructive process. On October 14, 1931, the transverse colon had filled to a diameter of over 1.5 inches and showed deep haustra. By October, 1933, the proximal half of the transverse colon had also shrunk down to a 3/8-inch diameter while the whole left side colon showed as a narrow ribbon (Fig. 4). What was there to do? The right sided colon was of good dimension, but from the hepatic flexure on there was only a thin ribbon left down to the last portion of the ampulla which was about the size of a large plum. I am sure if I had freed the hepatic flexure from its lateral peritoneal attachment and had brought it out obliquely through the right rectus muscle which latter would have acted as a sphincter, her stoma would have been very much less bothersome. H. L. Beie of Iowa City has used this "compromise colostomy" with good success, and it would probably have been the best thing to do under the circumstances. However, our young patient was willing to take all chances to have done away with the artificial opening. A woman wants to be clean and attractive. We deliberated much about a way out of this dilemma. When one entered the upper loop of the ileostomy with a thick sound the tip of it could readily be felt behind the uterus per vaginam. This made us try an anastomosis between this gut and the remnant of the ampulla.

On February 27, 1934, an ileo-proctostomy was made. Under spinal anesthesia vagina and rectum were well cleansed. The remnant of the ampulla did not reach higher than about the upper rim of the internal sphincter. A merthiolate-soaked sponge was inserted into this pocket. Then the posterior cul-de-sac was opened and the ileum loop in which the large bougie was felt was brought into the vagina and a linen purse-string placed in it. The one-half of a small Murphy button was then introduced and the suture tied around it. Then with a finger in the rectum, the musculature of the internal sphincter was laid bare in the vaginal incision and the other half of the button which had a wider rim than its partner was inserted through the anus, the mucosa nicked over it, and the two halves of the button closed. This looked like a very neat union. On account of the thinness of the gut wall, we did not dare to place additional sutures. A collapsible rubber drain was placed to one side of the ileum into the Douglas space. The opening in the vaginal wall was not sutured but simply packed lightly with metaphen

*After writing this paper I received word that the patient died suddenly of what seems to have been an embolus. Her mother writes she had been feeling exceptionally well this past summer.

moistened gauze to assure sufficient drainage and fixation of the loop. A free discission of the anus was made posteriorly to relieve all tension. The ileostomy opening was, of course, left open.

The postoperative course at first was reasonably good though the patient was quite weak. But after two weeks the button had worked loose from the rectum and fecal discharge came through the vagina. The button with the ileum gradually receded toward the sacrum upward, and a month after the operation (March 27) the button had to be removed through the vagina. A thrombosis developed in the left iliac vein and the patient died on April 6.

It was surprising that the rectal wall with the comparatively heavy muscular wall gave way though it contained the wider half of the button. It again demonstrates the importance of the peritoneal covering of the gut with its ready agglutination and fixation to other peritoneal surfaces. The rectal wall had no peritoneum to act promptly for the accomplishment of a union before the button became loose. An additional factor was probably a degree of colitic infection of the rectal wall. We had anticipated this possibility but relied on the large size of the lower half of the button and the fixation of the ileum loop by the packing. There was no peritonitis beyond the localized area of the drained parts in the bottom of the pelvis. A periproctitis as a result of the giving way of the button was undoubtedly the reason for the thrombosis of the iliac vein. In a similar case it would be advisable to fasten the button by a silk thread to a cross bar outside the anus or some similar fixation. The procedure gave the impression that it was a good way out of the necessity of a permanent artificial anus after ileostomy. Perhaps drawing the ileum into the rectum or an additional suture of the ileum loop to the edge of the transverse vaginal incision might have led to success. In case the gut is as thin-walled as in the described case it might be well to use the adjoining mesentery. A lesson to be had from this case is that the extra-peritoneal rectal wall cannot be trusted to hold much in similar cases.

Case 5.—On February 12, 1937, Mrs. A. L. came to see us. She had been married thirteen years, but had never been pregnant. She had been in a sanatorium for a nervous breakdown, and had suffered from colitis with much discharge of mucus for twelve to fifteen years. However, there had been no diarrhea until the last few days. In 1930 a caruncle of the urethra was excised and in 1933 an appendectomy and cholecystectomy had been made and a cyst of an ovary removed. Of late she had been very nervous, sleepless, and irritable. She was well built. Heart, lungs, abdomen, and urine appeared normal. By pelvic examination a rather large cyst was felt on the left ovary. There was some tremor noticed, but the basal metabolic rate was normal. There had been no marked loss of weight. The knee jerks were exaggerated. The cyst with the remainder of the ovary was then removed. It was of the size of a large orange. In addition smaller cysts of the right ovary were punctured and numerous pelvic adhesions divided.

This history is mentioned to give a picture and partial explanation of the neurotic state of the patient. She came back in January, 1938, with most emphatic complaints about her "colitis" and distress in the rectum. On examination we found a stricture of the rectum and a fissure of the anus posteriorly. A barium enema demonstrated a "marked shrinking of the lowest five inches of the rectum." Proctoscopy demonstrated a general bloody oozing from the rectal mucosa which was ulcerated. In her loud almost violent appeal for an absolutely necessary prompt help from her "insufferable" spasms she gave the impression of a desperate neurotic person ready to do most anything. An ileostomy was done on January 14, 1938, in the same manner as described in the previous case with a view to an easy closing when her wrath should turn toward this new situation. A transfusion was also given. Seven weeks later (March 3) she returned to Saint Paul for control. She was much better in every way, but complained of pain and cramps in the ileostomy area, for which injections of quinine and urea gave considerable relief. In October of the same year she returned, mainly for distress in the rectum. There were discharges of mucus and pus often with blood. Some pain was located at the midportion of the descending colon. However, a year later, March, 1939, fourteen months after the operation, she had gained from 120 to 160 pounds.

In September, 1939, she returned and asked to have the ileostomy closed. For nineteen months she had put up with the ileostomy, and she consented to take all responsibility if things should not turn out satisfactorily. It can readily be seen that this caused a favorable mental attitude toward probable future discomfort of minor degree, and we consented. The ileostomy was closed on September 26, 1939, after an injection of 300 c.c. of barley gruel into the efferent ileum loop had caused no trouble and the feces following had shown no blood. While in this case the ulcerative process was located at first mainly in the rectum, an x-ray study made by Dr. Medelman on March 22, 1939, had shown that the ulcerative lesion had extended upward since the previous examination, January 10, 1939. At that time it had involved only the rectum and lower sigmoid while now it extended to the lower part of the descending colon. Whether this extension had occurred in the early months after the ileostomy and had then been arrested remains uncertain. The steady though only very gradual improvement would make one think so.

The hospital chart records on the sixth day after the closure of the ileostomy seven defecations in twenty-four hours with intervals of from two to six hours. Nevertheless, she was allowed to go home two days later.

On February 17, 1940, she writes that she suffers much from gas and during the past months had three severe spells of pain which required morphin, but she winds up her report "on the whole, I think, I am getting along better than you ever expected I would, and I know that if I can get under conditions where I can give myself the care I should have as to work, rest, contentment, etc., I'll be all right as far as one can expect under the circumstances." She reports to have had of late from one to three bowel movements a day. Her weight is given as 165 pounds and her appetite as "unexcelled." What the future has in store for this patient is hard to predict inasmuch as recrudescences belong to the regular picture of ulcerative colitis. The fact that this patient fought energetically for the closing of the ileostomy surely is of marked psychological benefit, as it induces her to make as little as possible of bearable discomfort. On June 20, 1940, she came to our office. She looked very well and was apparently comfortable most of the time and pretty well satisfied with her condition. We advised a course of Bargen's serum and vaccine and neoprontosil[2] to be given by her home physician. Of recent days neoprontosil on account of its low toxicity, much less than some other sulfanilamide derivatives, has been used extensively by Bargen and has become a valuable drug for ulcerative colitis. Her local physician writes on September 23, 1940, that she quit using the vaccine after two months claiming she had no benefit and that sporadic outbursts of aggravation can invariably be traced to some psychic factor. She gained weight recently. Had it not been for the proctoscopic picture with the ready bleeding and ulcerated condition, one would think that the trouble was simply neurogenic. Her father had suffered from senile insanity.

Recapitulating these five cases:

All were women. The first one had a moderate chronic form where after much medical management an appendicostomy was done with a distinct temporary relief while the catheter was in place, but after removal of the catheter the condition became again more aggravated and remained about the same as before. The trouble has existed now for twenty-six years.

The second patient had an acute condition where an appendicostomy was followed by what seemed to be a complete cure for sixteen years. Then a relapse occurred of very serious character. It was promptly checked by Bargen's treatment plus neoprontosil. She has been well since then (twenty months).

The third, a very severe case, had an ileostomy with great benefit. The ileostomy opening was closed six and a half months later. She remained in good general health and was reasonably comfortable for ten years. The colon shows, however, serious changes.

The fourth patient had improved splendidly after ileostomy, but died after an unsuccessful attempt to anastomose the ileum with the remnant of the ampulla recti.

The fifth patient had an ileostomy which was closed nineteen months later (September, 1939) and up to the present (twelve months) since the closure of the ileostomy has remained satisfied.

These reported cases were clinically idiopathic ulcerative colitis. One has to exclude amebic dysentery which gives proctoscopically the picture of a rather normal not noticeably congested mucosa with here and there very small superficial ulcers. In bacillary dysentery, even in the cases later classified as chronic, the onset is most always acute, very often as part of an epidemic. The severe diarrhea is the outstanding feature. Tuberculous ulcers of the rectum occur late in a greatly emaciated patient, toward the end stage of a tuberculous process farther up, mostly in the cecum. The idiopathic ulcerative colitis, on the other hand, starts low in the large gut and progresses upward in the colon. The rectal mucosa is greatly and diffusely congested and bleeds readily. Ulcers are not easily recognized and are quite small. Bargen points out that at an early stage hyperemia and edema are seen followed soon by miliary little abscesses turning into small ulcers, which later become confluent.

Surgical Treatment

The least interfering procedure but also the least effective is an appendicostomy, followed by plain water irrigations. In general Bargen is surely right when he deprecates much flushing of the colon, as rest for the gut is important. Nevertheless, this procedure may have a beneficial influence in an occasional recent case as our second case showed. Whether the appendicostomy had much to do with the favorable outcome may be considered doubtful. Many factors come into play, not the least of which are psychic. McKittrick reports on 149 cases admitted to the Massachusetts General Hospital during the twenty preceding years. There were four appendicostomies, with two deaths. Apparently the appendicostomies were mainly performed in the earlier years of this period. Our two cases were our earliest ones. We were uncertain what to do and feared to do something that could not be undone. H. L. Beie discussed McKittrick's paper and reported on thirty-nine patients operated upon at the Iowa University Hospital. He had had very discouraging results with ileostomy (twelve cases) and therefore went back to appendicostomy and cecostomy as a compromise operation. He often saw a striking degree of improvement in the twenty-one patients operated upon in this manner. Among these twenty-one cases there were five deaths, two of which occurred in the hospital and three died subsequently from the disease. There was one cure which clinically after three years could be classed as complete. The bowel in this case is, however, not cured, as demonstrated by the roentgen findings. The bowels move only once a day. Another patient gained 20 pounds, has the catheter still in place and does heavy farm work. His bowels move twice a day. Eight other patients showed slight to considerable improvement. One patient had no benefit at all, and Beie thinks he was made worse. Of the twenty-one cases five had subsequent colectomies or colostomies. He declares to have learned that if this method is employed the tube must be worn permanently, except in a very lucky case. I have quoted Beie more or less in detail because his views appeal to me very much. Of special interest is that he performed colostomy in eleven cases as a "compromise operation" between appendicostomy and ileostomy in cases where only the left side colon was affected. In four cases he made a colostomy on the midportion of the transverse colon notwithstanding the fact that this part of the bowel was moderately diseased though less than the lower regions. When this can be done, it is of very great advantage inasmuch as the patient is immeasurably more comfortable than with an ileostomy.

Ileostomy may be the best immediate way out of serious trouble, but it leaves mostly a very unsatisfactory situation. At the Mayo Clinic it has been less and less employed for this reason. McKittrick reports fifty-four ileostomies among his 140 cases, with fifteen deaths. He very appropriately declares that in order to be satisfied with an ileostomy, a patient must have experienced what misery ulcerative colitis brings on. All three of our ileostomy patients admitted that they were relieved of unbearable misery but later on would not put up with the state of affairs and implored us to close the opening. They were all women, or rather two women and a young girl. A man is perhaps a little less sensitive, but a woman cannot be happy unless she is clean and attractive. The result of closing the ileostomy in two of the reported cases is therefore of interest even if they should only represent exceptional conditions. One had the ileostomy closed and was satisfied and reasonably comfortable for ten years afterward. The other who had her ileostomy closed a year ago is rather satisfied so far.

All surgeons appear to admit that ileostomy with exceedingly few exceptions leaves a lamentable state of affairs. It is best done in the most simple manner through a grid-iron incision. R. H. Miller in the above mentioned discussion of McKittrick's paper lays

stress on this point, and he warns against exploration. Much handling of the gut is to be avoided as it may set up a general peritonitis. He compares the condition of the gut wall with that of a canvas tent in a rain storm. It remains dry inside until you draw a finger along it, when it starts to drip. In one of our cases we mentioned that getting hold of the gut caused hemorrhagic suffusion. The intestine, therefore, has to be handled with utmost care.

In looking for an improvement of the condition following ileostomy it appeared to me one could lead the gut on a slant through the rectus muscle. This would create some sort of a sphincter. In addition there would be less of a tendency toward an eversion of the gut which happens not infrequently. A catheter might be used for evacuation.

If the ileostomy is done in such a manner that it can be closed later on rather easily, the decision to have such an artificial opening established at least temporarily is made easier for the patient.

Colectomy remains as the final trump card which the surgeon holds. While it is not as formidable an operation as it might appear, the preservation of the normal rectal sphincter would be of great value where the case allows it, and under such circumstances a trial like in Case 4 with or without a colectomy later on seems permissible.

The course of the disease with its remissions over long periods of time, and the very harmful influence of mental upsets make one hesitate in accepting the condition as a straight infectious process. Fear, wrath, and similar excitement act strongly on the autonomic nervous system. Adrenin is poured out, not only by stimulation of the adrenals, but the ends of the sympathetic fibres create locally adrenin on stimulation. Daily observation tells us that in an infected tissue the nerves are abnormally sensitive to stimulation. Inasmuch as even in a normal individual severe peristaltic contraction of the colon may be observed in sudden fear, the spasms of an infected gut in an individual with a very labile mental equilibrium would naturally be much increased. And now another factor enters: in thrombo-ulcerative colitis the infection reaches deeply into the gut wall. While rest is the paramount requisite for inflamed tissues to heal by not interfering with Nature's repair work, we can readily recognize the deleterious effect of spasms. The statement of our last mentioned patient that acute aggravations could invariably be traced to mental upsets is significant. And still another factor is to be considered. Physiologists have shown that adrenin is only one of the substances produced by nerve stimulation. Deeper changes in the chemism of the parenchymatous organs through nerve influence may have to be reckoned with. This would be in harmony with the good results by parenteral liver therapy as reported recently by G. Cheney.[3]

Even this, our very small experience, demonstrates the great variation in individual patients. Though they were all surgical cases, the hope for the future must lie in the medical treatment, which with serum and vaccine and especially neoprontosil has produced noteworthy results and for this reason ought to be tried before resorting to surgery in all but the most violent acute upsets.

Discussion

Albert M. Snell, Rochester: It is always a pleasure to hear Dr. Schwyzer recount his experiences and his remarks tonight are of particular interest to those who have had any experience in the treatment of ulcerative colitis.

There are one or two recent points in treatment which can be mentioned. The first has to do with the nutritional aspects of the disease. It has been noted for a long time that deficiency states of one type or another are not uncommon complications in advanced ulcerative colitis. It is believed generally that these are due to faulty absorption of vitamins from the intestinal tract. In some cases it is apparent that the defect in absorption may be considerable, since patients may present themselves with pellagra, peripheral neuritis or marked deficiency in prothrombin. Mackie reported that 63 per cent of the patients with ulcerative colitis who were under his care at the Roosevelt Hospital had nutritional disturbances of some type. It is now considered good practice to use generous supplies of the vitamin B complex and other vitamins in treatment of the disease; some rather encouraging results have been noted.

The use of derivatives of sulfanilamide in treatment of the condition is still being investigated. As is generally known, fatty metamorphosis of the liver may develop in cases of ulcerative colitis; hence, such patients may be vulnerable to the hepatotoxic effect of some of these drugs. I have seen one or two instances of subacute atrophy of the liver following their use. A new compound, sulfaguanidine, appears to be of some promise for it is less toxic and absorbed more slowly than some of the compounds of sulfanilamide now in general use. However, our experience with sulfaguanidine has been limited.

Dr. Alfred Hoff, Saint Paul: I was very much interested in this paper and in Dr. Snell's discussion. I have followed one case for twenty-one years, which I think is worthy of presentation at this time. My first contact with the patient was in 1919 when she was suffering with an acute fulminant ulcerative colitis. She remained in the hospital four months; her temperature ranging from 102° to 104°, with frequent stools containing mucus, blood and pus. She became marasmic, losing about 50 pounds in weight, and was confined to bed for a total of six months. She gradually recovered her weight loss and, except for some abdominal discomfort, remained well for a period of ten years, when she relapsed and again went through the same severe infection with a course almost identical with that of the first attack. It had the same long duration and severe symptoms.

I saw her last week—twenty-one years later. She now weighs 133 pounds and says that, except for occasional abdominal cramps with slight diarrhea, she is in good condition. A proctoscopic examination in 1934 showed no ulcerations and the rectal folds were not indurated. A barium enema at that time revealed an absence of haustrations involving the colon generally with constriction of the lumen of the bowel in the pelvic colon.

Another case of interest is an autopsy proven case

of chronic ulcerative colitis in a man sixty-nine years of age. It was associated with a severe depression of the bone marrow, showing a marked anemia and a progressively more profound leucopenia involving especially the granulocytic series. No immaturity of cells was noted and a postmortem bone marrow study at Dr. Downey's laboratory revealed a severe leucopenia in the marrow with invasion of lymphocytes while the neutrophils in toto amounted to only 8.5 per cent of the total number of cells. The bone marrow, therefore, was regarded as not completely agranulocytic. During a period of six weeks' observation with repeated blood studies, his hemoglobin averaged 52 per cent, the high 68 per cent and the low 37 per cent shortly before death. The average of seven erythrocyte counts was 3,000,000. The leukocytes on admission to the hospital numbered 1,600 with 38 per cent neutrophils, 49 per cent lymphocytes, 10 per cent monocytes, 2 per cent eosinophils and 1 per cent basophils. During the following six weeks, they progressively fell lower until the day before his death his leukocytes numbered 130 cells with 36 per cent neutrophils and 64 per cent lymphocytes. No immaturity was found. Terminally, he developed a severe membranous sore throat with chills and high fever, so often seen in blood dyscrasias.

In view of his blood findings, one is hardly justified in considering this to be a case of true agranulocytosis. No history of any medication was present. An effort was made to stimulate his bone marrow function with the use of liver extract and pentnucleotide.

Of interest also is the fact that this patient was a bachelor living alone on a small farm, where, for a considerable period of time, his diet had been very inadequate.

Dr. James Johnson, Minneapolis: There are two questions I would like to ask Dr. Schwyzer, who has had vast experience along this line:

1. Does he not feel that once an ulcerative colitis, always an ulcerative colitis?
2. Does he believe there is any one thing that causes ulcerative colitis; or, at least when we meet these cases, isn't there a great multiplicity of causes responsible for the continuation of the condition?

I have had patients get well on Bargen's vaccine, tomatoes, peanuts and sunshine. For example, I have placed them on restricted diets and they have constantly become worse; and then, in desperation, they would go ahead and eat everything they wanted and get well. There is, no doubt, a variety of causes, perhaps largely on a deficiency basis.

Dr. Arnold Schwyzer (in closing): First, to answer the question of—once a colitis always colitis. That theory was proclaimed vividly by Dr. D. F. Jones at the mentioned meeting of the American Surgical Association. In his opinion, there would always be a colectomy in the end if the patient did not die beforehand.

In the paper I reported the two cases, one well for sixteen years and the other ten years; well surgically, but not anatomically. Some cases improve but you cannot foresee the course. There is always the question whether the improved ones had the same condition as the others. Bargen has given this subject a very great amount of attention, and he had such a large percentage of good effects from serum and vaccine that this fact remains of outstanding importance.

In the one case I mentioned, the woman had been in bed for a whole year with terrible misery and then, after vaccine, serum and neoprontosil, in three weeks feels well and never feels she needs further attention.

The fifth one of my cases well demonstrates the nervous influence. Every time she has an upset, it is due to some psychic irritation.

Under such conditions, the autonomic nervous system is especially much worked up. We know that from the very ends of the activated motor nerves there is a formation of adrenalin. As the nerves of the muscular coat of the gut are irritated by the inflammation, there is going to be more and worse spasms, and spasms are the worst thing for the healing of the infection. To have healing, there ought to be rest; so in these cases we have a vicious circle. We have to figure also with an effect on parenchymatous organs as well by nerve action as purely chemically from toxic products.

As I mentioned in the paper, Cheney reports very good results from parenteral administration of liver extract. The causative micro-organisms may be different in different patients and each case thus remains a problem of its own.

THE TREATMENT OF ACUTE CORONARY OCCLUSION BY LONG CONTINUED USE OF OXYGEN THERAPY

An Experiment

C. N. Hensel, M.D., F.A.C.P.

Saint Paul, Minnesota

For years the only remedies for the treatment of acute coronary thrombosis were bed rest and morphine. Occasionally a case was encountered in which morphine did not relieve pain, or in which the circulation seemed to fail; then oxygen by means of the oxygen tent was supplied, often with beneficial results on both pain and circulatory support.

In December, 1938, Dr. Walter Boothby demonstrated before the Minnesota Society of Internal Medicine his B. L. B. mask for giving 100 per cent oxygen. It was shown that oxygen by this method was much less expensive, easier to apply, better tolerated than the tent, and above all, that it delivered approximately 100 per cent oxygen to the trachea, whereas the oxygen content of the tent, at best, was only 60 per cent.

Boothby further demonstrated that by this method of giving 100 per cent oxygen, the arterial blood would contain 10 to 15 per cent more oxygen. The amount of supersaturation would depend on the level of the hemoglobin and on the rate of the circulation.

He stated that under normal conditions, as the blood passes through the capillaries, the rate of circulation is so regulated that it gives up about one-third of its oxygen to the tissues and enters the veins about 60 per cent saturated, at which degree of saturation the partial pressure of oxygen in the capillaries would be approximately 35 mm. of mercury. When the rate of circulation is decreased, the blood may give up nearly 80 per cent of its oxygen as it passes through the capillaries; therefore the venous blood is only 20 per cent saturated and exerts a partial pressure of oxygen of only 14 mm.

This lowered capillary tension probably reduces capillary tone, favors capillary dilatation, and increases circulatory stasis. In most cases of acute coronary thrombosis, there exists in addition to pain, a marked drop in blood pressure and signs of shock.

Because of the above factors oxygen therapy is indicated in the treatment of acute coronary thrombosis and has been used successfully during the past two years

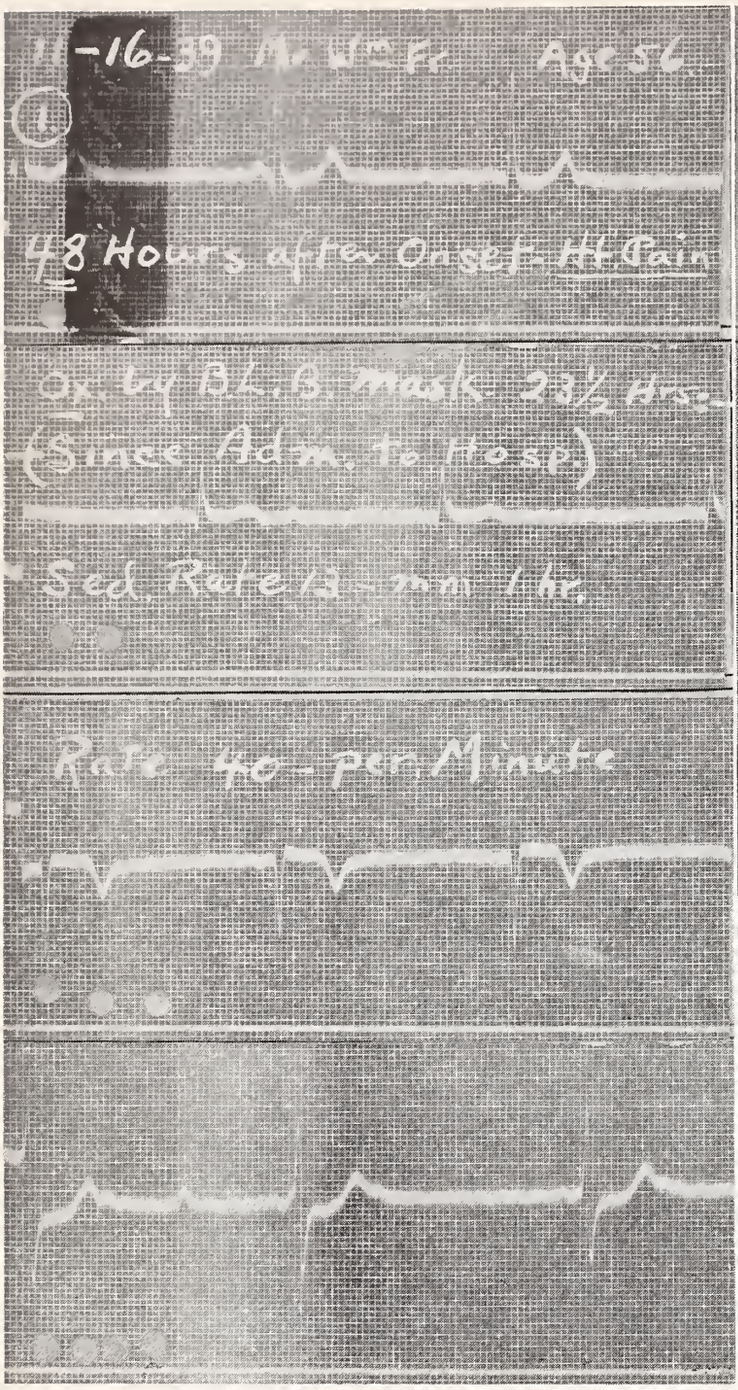

Fig. 1. Electrocardiogram taken forty-eight hours after onset of heart pain shows a rate of forty beats per minute, and a slurring take-off of the T wave in leads 1 and 2, and a flattened T wave in lead 2 and crescentric downward deflection of the T wave in lead 3.

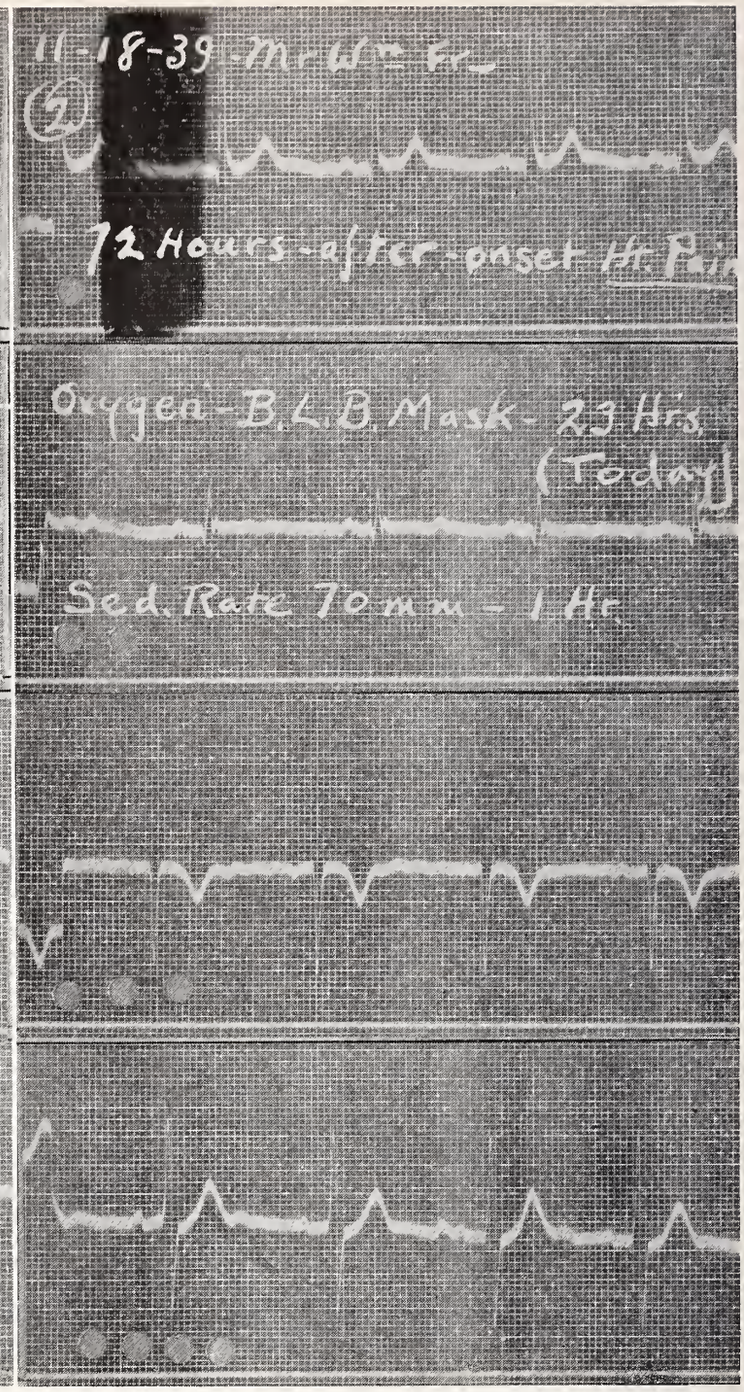

Fig. 2. Electrocardiogram taken seventy-two hours after onset of pain shows a rate of sixty beats per minute and a rising in the take-off of the T wave in leads 1 and 2, and an increase in the slurring in lead 2. T_2 is now iso-electric and the downward descent of T_3 has increased.

by the B. L. B. mask. Its use has usually been discontinued at the end of twelve to twenty-four or forty-eight hours, when the signs of shock had abated and pain had disappeared. However, I encountered a case of acute coronary thrombosis in a man, who, because of pain and marked cyanosis, needed to have the oxygen therapy by the B. L. B. mask pretty continuously for fourteen days, before his cyanosis could be controlled.

From then until the twenty-eighth day oxygen therapy was continued on theoretical grounds in gradually decreasing amounts.

Case History

The patient, Wm. Fr., aged fifty-five, a wholesale meat dealer, was admitted to the Miller Hospital by ambulance at 3 p.m., November 15, 1939, suffering from substernal pain radiating to the shoulders and arms of twenty-four hours' duration.

History of Complaint.—A business executive, under great strain for the previous ten years, and while apparently in good health and strong (often shouldered 200 pounds of beef easily) left an exciting Downtown Quarterback's luncheon meeting and walked five blocks to his parked automobile. During his post-prandial walk he experienced severe substernal pain but after a ten-minute rest was sufficiently relieved so that he made calls on his trade during the afternoon. He returned to his home complaining of a dull ache beneath the sternum and spent a restless night because of this substernal ache.

He worked till noon of the next day, but returned home because of the pain and called the family physi-

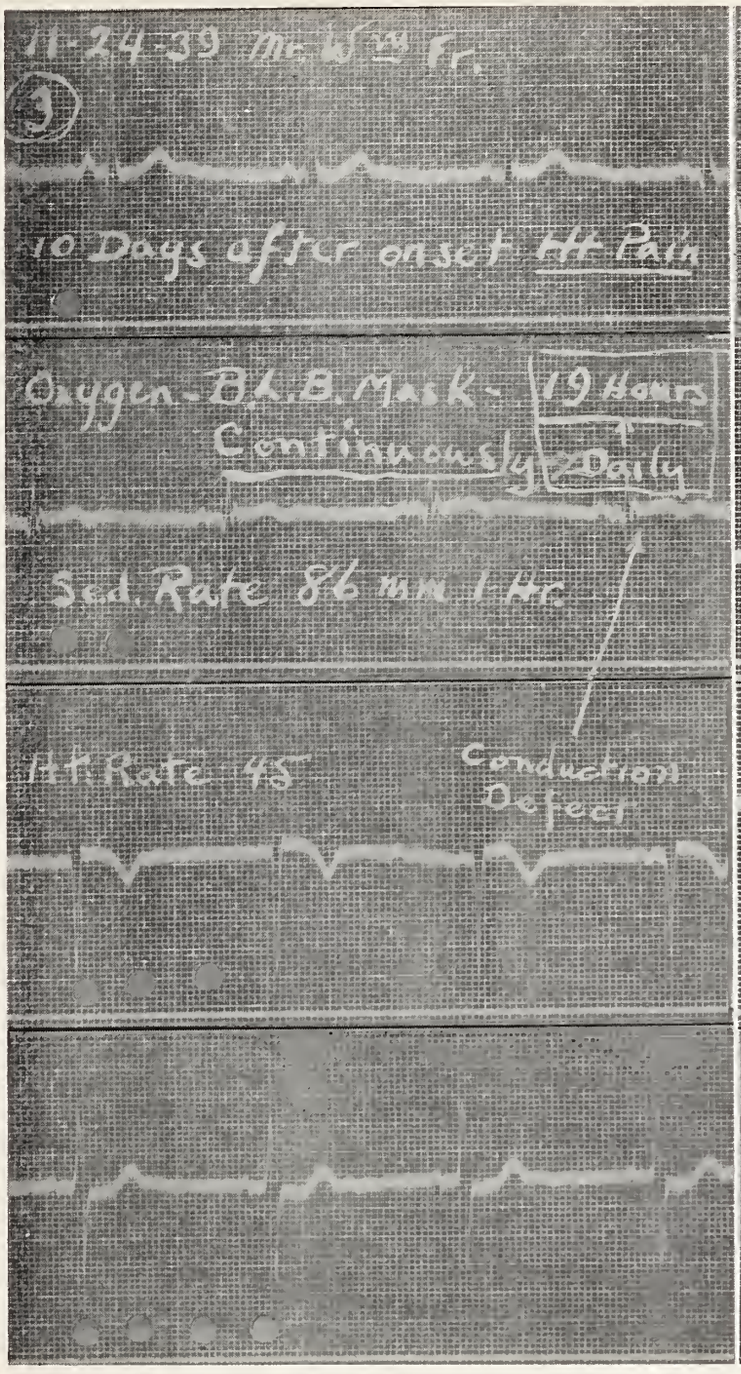

Fig. 3. Electrocardiogram taken ten days after onset of heart pain shows a heart rate of forty-five beats per minute, and an increase in signs of slurring of take-off of T_2, and a beginning downward descent of T_2.

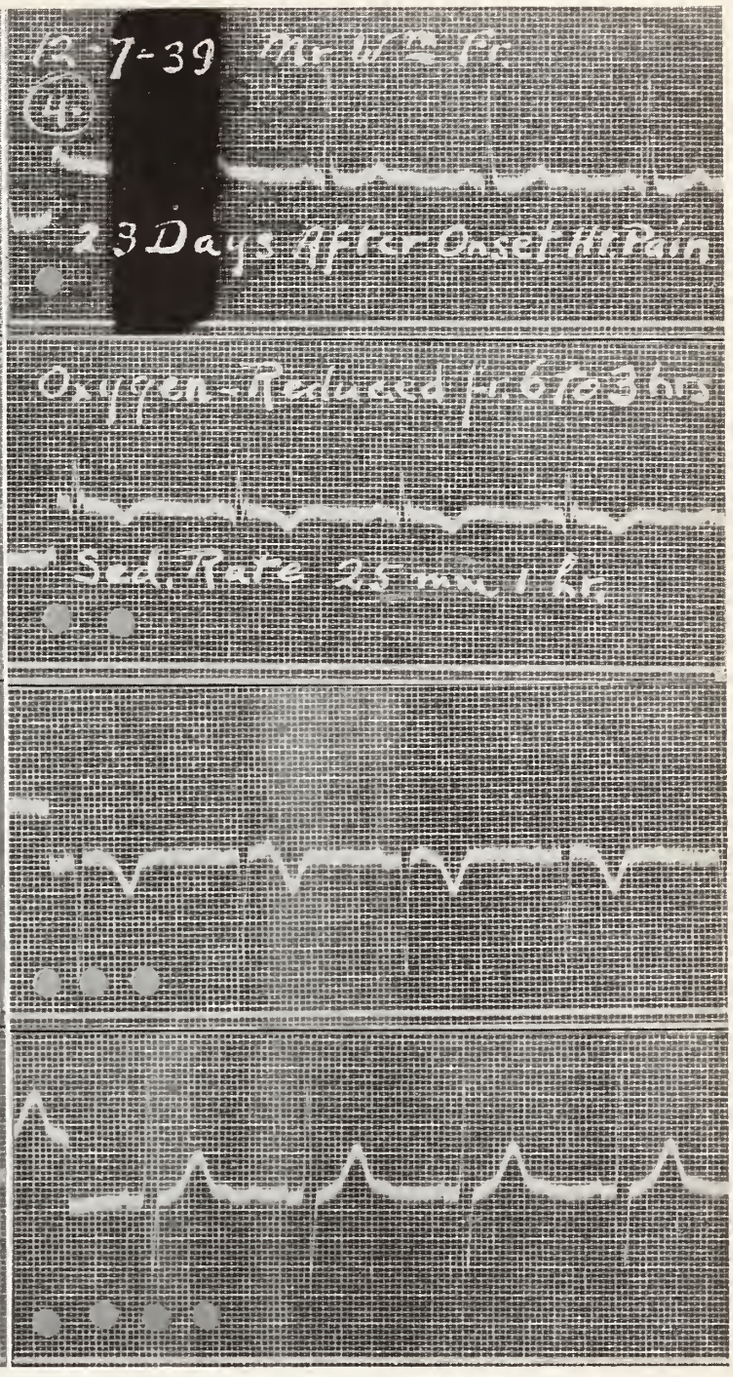

Fig. 4. Electrocardiogram taken twenty-three days after onset of pain shows a heart rate of sixty beats per minute, a flattening in the contour of T_1, and a further inversion in T_2. In lead 2 the T wave shows a crescentric downward deflection. The change in the contour of 2 and 3 is suggestive of an involvement of the branch of the right coronary artery.

cian. He was seen at home by the family physician about 2 p.m. (twenty-six hours after onset of pain) with a heart rate of 90 and a blood pressure reading of 160/90, and was sent to the hospital with a diagnosis of probable coronary occlusion.

When first seen by me the patient was in a state of profound shock. There was an ashy grey pallor in his face, combined with a deep cyanosis of the lips, cheeks, and ears. His heart rate was 30 beats per minute, the rhythm was regular, the tones were faint and distant in character. No murmurs were elicited, and there were no congestive rales in the lungs or passive congestion of the liver. From the patient's facies and general condition, death appeared imminent. Blood pressure 94/54.

Treatment.—Continuous oxygen therapy (100 per cent) by the B. L. B. mask was started, and morphine and glucose were given. Diet was limited to 500 calories a day.

Diagnosis.—Slow coronary occlusion with heart block; condition critical.

Course.—Within one-half hour after giving morphine, gr. ¼, by hypodermic, and applying oxygen, the pain was reduced in severity, and the patient appeared to be resting comfortably. At the end of three hours of 100 per cent oxygen therapy by the B. L. B. mask, the state of marked cyanosis and shock was improved, the pulse rate was recorded at 60 beats per minute, and the blood pressure at 145/85. During the night the pulse rate varied from 60 to 42 beats per minute.

The second day in the hospital and forty-eight hours after onset of substernal pain, the patient's condition was still critical. The heart rate was 44, rhythm regular, tones faint and distant. Blood pressure 115/85. When the mask was removed ten minutes for light breakfast, the substernal pain reappeared, and later when the mask was removed while an E.K.G. was taken the pain again reappeared. The patient was

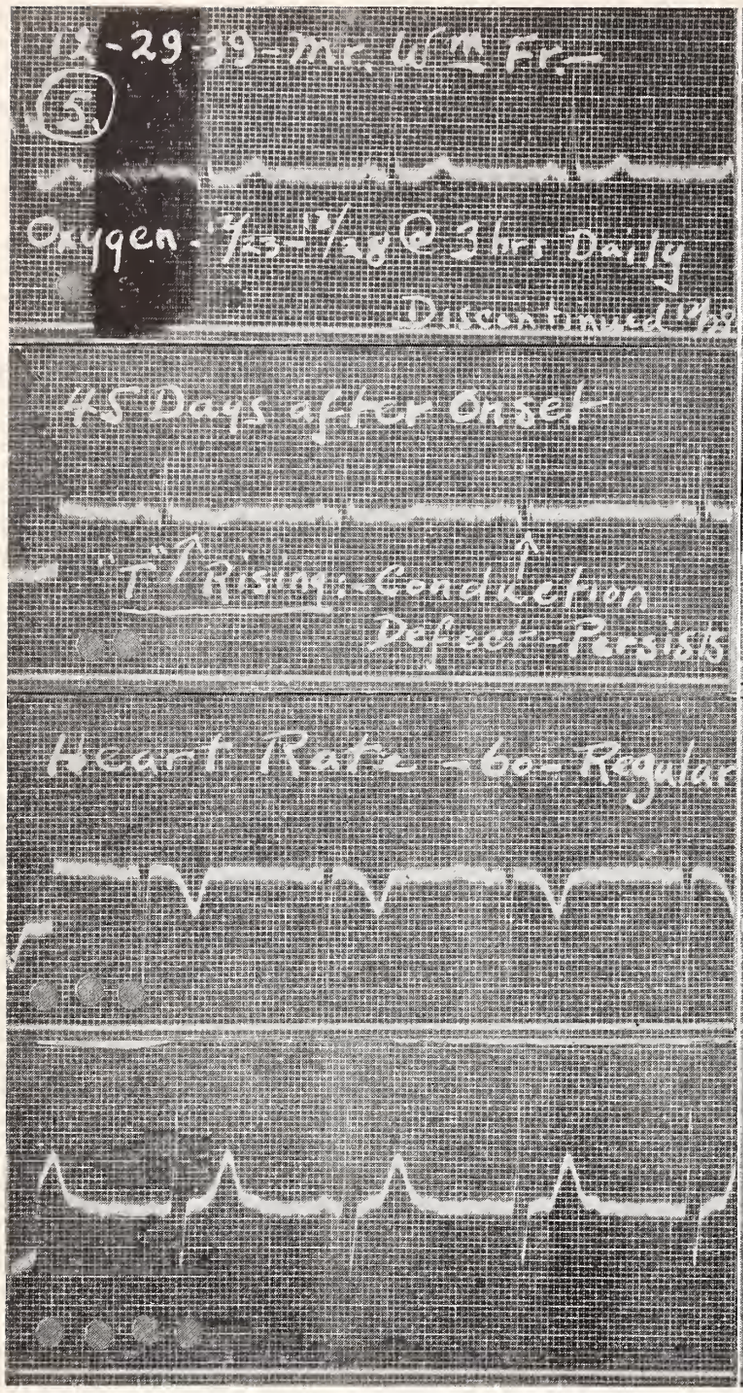

Fig. 5. Electrocardiogram taken six weeks after onset of heart pain shows a heart rate of sixty-two beats per minute, a persistance of the conduction defect in leads 1 and 2, but a rising of the T_2 to a nearly iso-electric position.

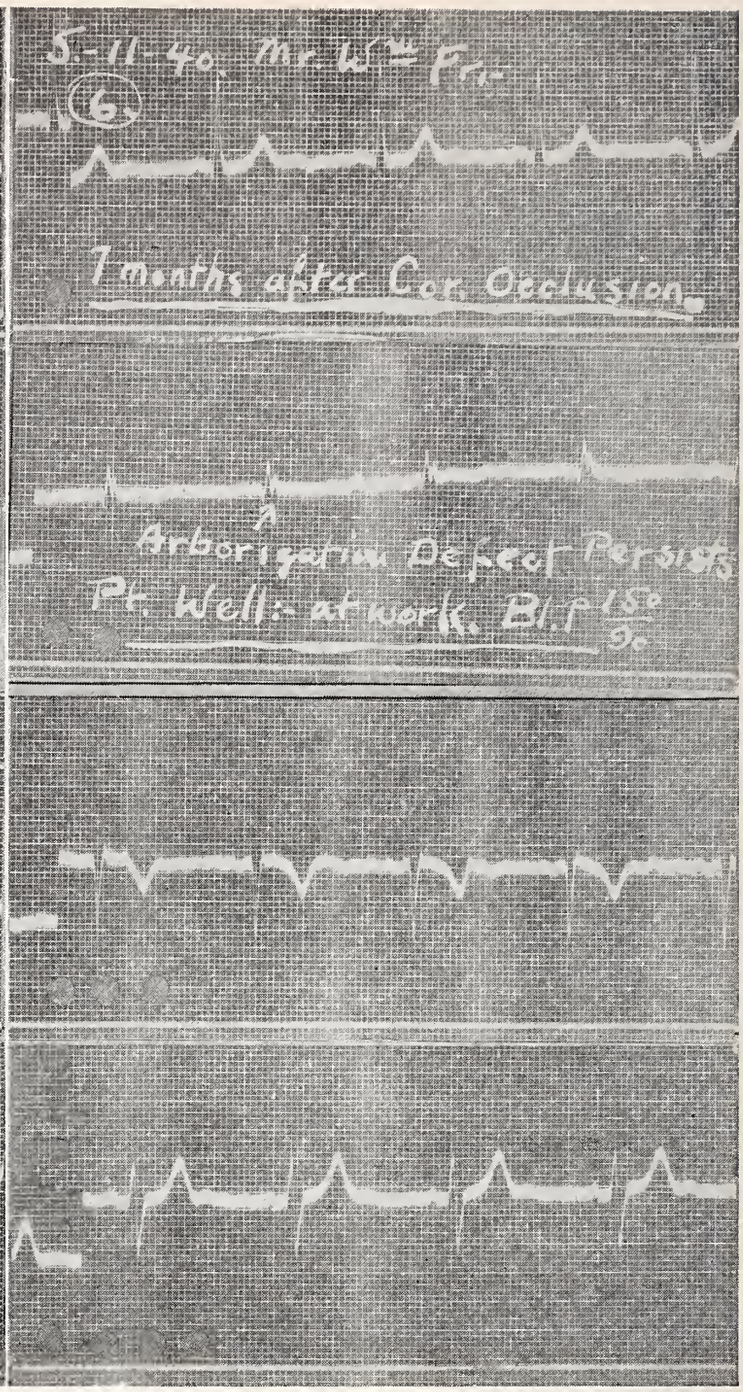

Fig. 6. Electrocardiogram taken seven months after onset of heart pain resulting from coronary occlusion. Shows a heart rate of sixty-two beats per minute and a regular rhythm. PR interval is .16 seconds, QRS .08 seconds, and RT .44 seconds. The T_1 is of normal contour and good height, and the take-off is returned to the normal position with only a minimal amount of slurring in evidence. In lead 2, QRS shows a marked stunting and notching in the descending limb, characteristic of aborization defect. The T_2 is flat in contour and diphasic in outline. The T wave in lead 3 still shows crescentric downward deflection. This record shows that there has been involvement both of the right ventricular wall and the interventricular septum.

without a mask but a half hour of the second twenty-four hours of his illness.

Sedimentation rate was 13 mm. at the end of 1 hour. Hemoglobin 15.6 gm. (93 per cent). Leukocytes 11,800.

On the third day in hospital, the mask was off a total of 1.5 hours and pain and cyanosis returned.

On the fourth day in hospital the patient complained of tightness and pain around the heart. A coarse pericardial friction rub was clearly audible. Sedimentation rate was 70 mm. at the end of 1 hour. Temperature 101° (rectal).

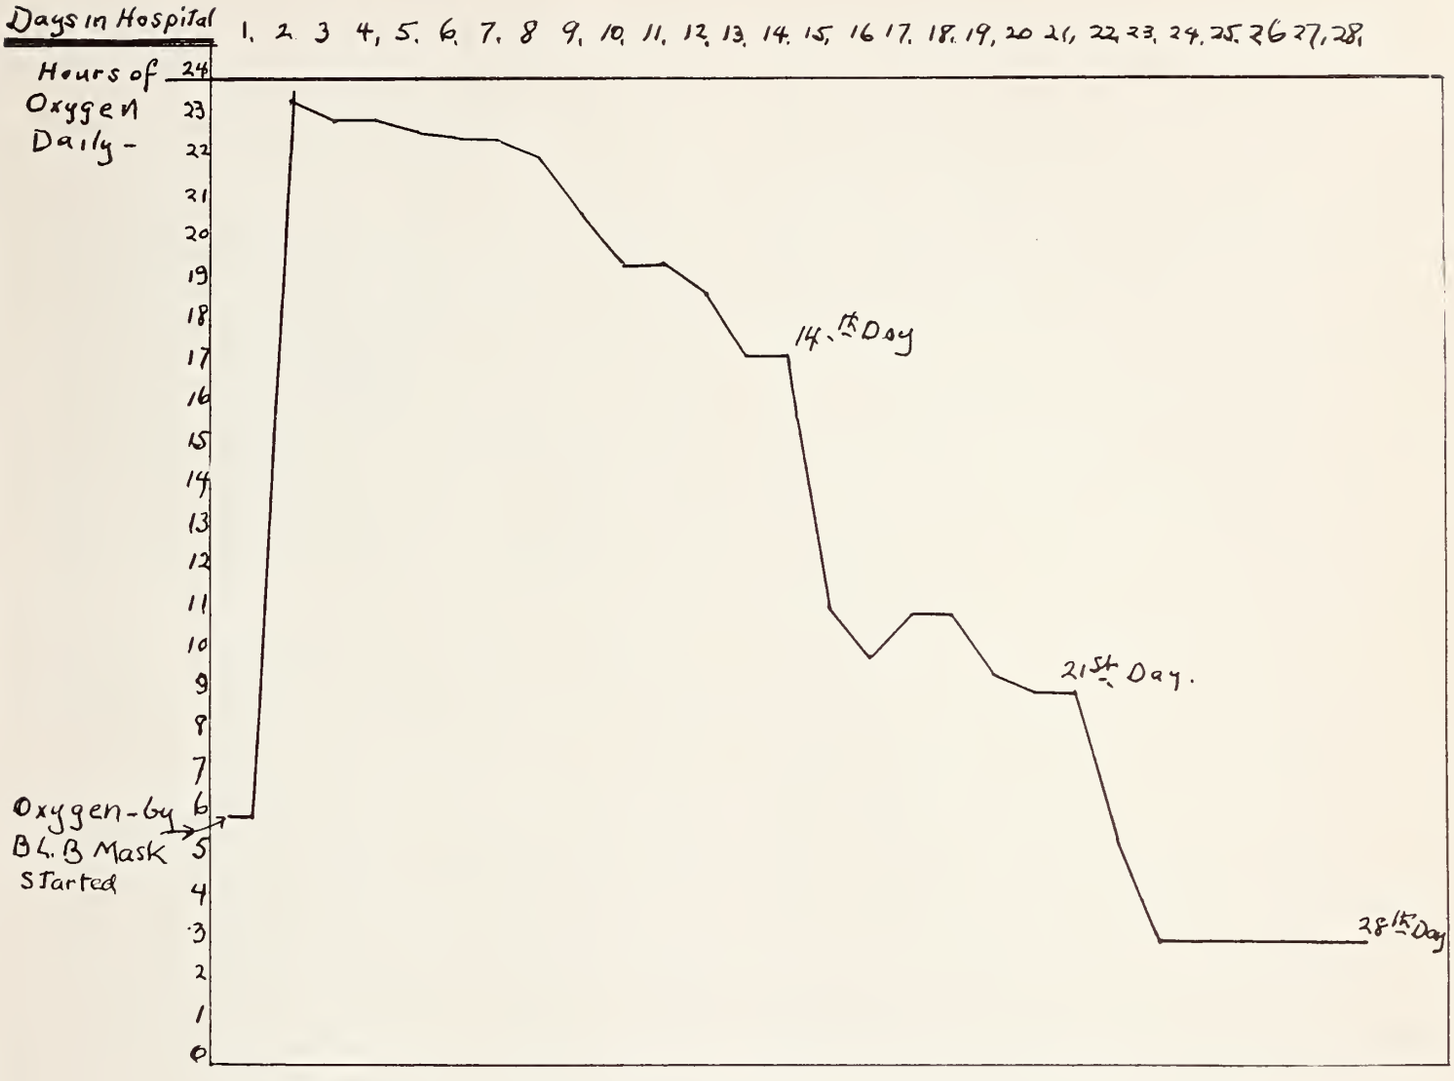
On the fifth day in the hospital the friction rub over the pericardium was absent. The oxygen mask was off 20 minutes four times this day but cyanosis was marked when the mask was off.

On the seventh day in hospital when the oxygen mask was off for thirty minutes, there was no dyspnea, no reduction in pulse volume, and no change in color. The pulse rate was forty-eight beats per minute, respirations twenty per minute. When the oxygen mask was off for forty consecutive minutes, the lips gradually darkened to cyanosis. The oxygen mask was off for a total of ninety-five minutes.

On the eighth day in the hospital, the oxygen mask was off for three periods of forty minutes each, a total of 120 minutes. Slight periodic pain in the cardiac region, slight cyanosis was present when the mask was off.

On the ninth day in the hospital, the oxygen mask was off for five periods varying from fifteen to sixty minutes. No heart pain occurred, and no cyanosis developed. The total time the mask was off was three hours, twenty minutes.

CHART I. GRAPH SHOWING THE HOURS OF OXYGEN ADMINISTRATION DAILY



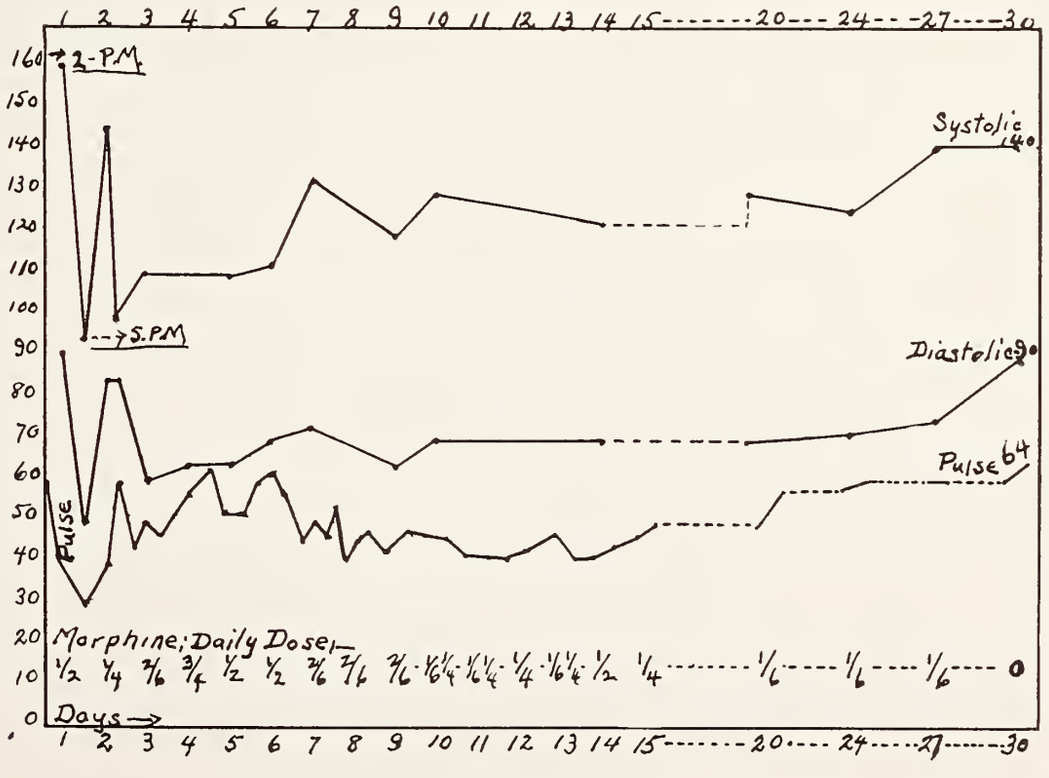


CHART II. COURSE OF BLOOD PRESSURE AND PULSE THROUGHOUT THIRTY DAYS OF SICKNESS

On the tenth day in the hospital, when the oxygen mask was off one and one half hours, the lips became cyanotic towards the end of the time, but no dyspnea developed. There was no change in pulse rate or volume. The total time the mask was off was four and a half hours at intervals of from one half to one and one half hours.

The quantity of food allowed daily was gradually raised to 1200 calories in the past few days.

On the fourteenth day in the hospital, the total time the oxygen mask was off was six hours and fifty minutes at intervals from one half hour up to three hours. Cyanosis was absent all day and in its place there appeared a "ruddy" color to the face similar to that in polycythemia vera. Pulse was fifty-two beats per minute, rhythm regular, and blood pressure 122/70.

TABLE I. SEDIMENTATION RATE

(Note marked early increase and later decrease)

Date	Sedimentation Rate Per Hour	
11-16-39	13 mm	2nd day
11-18-39	70 mm	4th day
11-23-39	86 mm	9th day
12- 2-39	50 mm	17th day
12-13-39	25 mm	28th day

Comment

To one watching this patient as closely as I did, the value of continuous 100 per cent oxygen therapy by the B. L. B. mask seemed without question a probable life-saving measure, during the first few days.

The relative bradycardia with a resultant slowed circulation rate, probably made heavy drafts on the oxygen content of the circulating blood, resulting in marked cyanosis.

I reasoned that if the capillaries in the cheeks show cyanosis, then the capillaries in the heart muscle must also show cyanosis (registering tissue anoxemia), and as long as this condition existed, a supplemental supply of oxygen was necessary and should be given.

I was aware of Dr. Boothby's caution in his article on "Oxygen Therapy" in the July, 1939, issue of *Medical Clinics of North America; i.e.,* "until further experiments have been carried out, it is inadvisable to administer pure oxygen for longer than two days." But in this particular case I had no alternative but to continue oxygen therapy as long as cyanosis persisted.

The only objectionable symptoms which arose during the long period of continuous oxygen therapy were motor restlessness during sleep, a tendency to wakefulness, mental excitability, and talkativeness during the night. These symptoms were promptly reduced and often controlled by moderate doses of morphine hypodermically. While under the oxygen mask through the day, the patient often complained of a disagreeable sense of warmth in the skin.

On the favorable side there was the apparent effect of the oxygen therapy on the intestinal tract. After the sixth day the abdominal distension disappeared, the walls became soft and pliable, the patient passed flatus freely and soon began to have daily, spontaneous, easily expelled bowel movements.

Finally it seemed reasonable to believe that such oxygen therapy could not have been harmful, when a patient who had been so critically ill at the beginning of treatment could look so splendidly well at the end of fourteen days of such therapy. However, because of the above mentioned objectionable symptoms, it was decided now to withdraw the supplemental oxygen therapy cautiously, not knowing how the human organism would react during quick withdrawal. Therefore the time the oxygen mask was off was gradually increased from six to twelve hours without any deleterious effect.

Now, instead of dispensing with oxygen therapy as quickly as possible (since cyanosis was no longer present), it was decided to continue oxygen therapy on theoretical grounds, for as many hours a day (up to twelve hours) as the patient would tolerate it.

Since the process of healing of cardiac infarcts, following coronary artery occlusion, is characterized during the first few days by a liquefaction necrosis of the muscle fibres, followed by the ingrowth of connective tissue fibres and new blood vessels, I reasoned that a supplemental supply of oxygen should facilitate tissue repair and possibly reduce the amount of muscle necrosis.

Therefore, since the patient had become well trained in the use of the oxygen mask and was exceedingly cooperative, I explained my theories to him and asked him to aid me in this experiment. This he consented to do.

The patient took oxygen by the B. L. B. mask for the next seven days, namely, up to the twenty-first day of his illness, in decreasing daily amounts, from eleven to ten to nine hours. It gradually became apparent that, since the disappearance of the cyanosis, the patient did not tolerate oxygen therapy as readily as he had done previously. He complained of a disagreeable sense of bodily warmth when the mask was on and desired extra coolness and ventilation in his room. Some of these complaints seemed to be nervous because when most of the oxygen was given at night and the patient received an injection of morphine sulphate, grains 1/6, by hypodermic, before the mask was applied, he got through the night fairly well and slept at long intervals.

By the twenty-first day it was felt that the necrotic process in the infarct was no longer going on, and that the connective tissue repair was in full swing, so that on theoretical grounds supplemental oxygen would no longer be necessary. So it was planned to wean the patient gradually from his supplemental oxygen supply.

For the next two days the hours under the B. L. B. mask were cut from nine to six hours without any untoward incident. For the next five days the hours under the mask were cut to three in each twenty-four-hour period. Oxygen was usually given for three hours each evening, always preceded by an injection of 1/6 grain of morphine sulphate by hypodermic.

By this arrangement the patient was freed from the annoyance caused by the long continued use of the mask and usually slept quietly for the ensuing three hours.

On the twenty-eighth day of his illness, all oxygen therapy was terminated without any apparent deleterious effect. With the stopping of the oxygen the daily hypo-

dermic injection of 1/6 grain of morphine sulphate was also stopped. Following the stopping of the morphine no craving for the drug or "withdrawal symptoms" appeared. The patient did not receive or appear to need any more morphine.

Patient's Condition at End of Four Weeks

Four weeks after the onset of an attack of acute coronary artery occlusion, treated by flat bed rest and continuous oxygen therapy by the B. L. B. mask, the patient appeared to be in good physical condition. The color of his cheeks had been "ruddy" from the fourteenth day on. His blood pressure was 140/74; heart rate was between 54 to 60 beats per minute, rhythm regular. The apical first tone which was formerly muffled and distant in character had increased in force and definition. The walls of the belly were soft and pliable and patient had had one to two soft, spontaneous stools daily since the end of the first week. Such a relaxed belly, freedom from gaseous distension and spontaneous stools may be attributed to the use of oxygen.

At this time the examination of his blood revealed a hemoglobin of 16.8 gms. (101 per cent), an erythrocyte count of 5,950,000, and a leukocyte count of 13,050, the blood picture of a mild polycythema vera.

That the oxygen therapy did not produce this blood condition is probable from the fact that his hemoglobin on admission was high, 15.6 gm. (93 per cent) and also from the fact that his wife reported that a "ruddy" complexion was his customary appearance.

For the balance of his course the patient received the usual orthodox treatment of graduated sitting up and graduated walking. He was transported to his home by ambulance on the forty-ninth day of his illness, where he continued his schedule of slow rehabilitation.

At the end of three and a half months from the onset of his illness, he appeared to be pretty completely restored to his usual health. The patient was last seen July 22, 1940, at which time he appeared to be well. He stated that he worked every day and experienced no heart pain, dyspnea, swelling of the ankles, or undue fatigability. His blood pressure was 160/80, and his heart rate was sixty beats per minute; the rhythm was regular and no murmurs were elicited.

A paper by Drs. Mallory and White of Boston, on "The Speed of Healing of Myocardial Infarction" which appeared in the *American Heart Journal* for December, 1939, lends some credence to the theory on which the long continued use of oxygen therapy was applied in this case. They studied the hearts of seventy-two human patients who showed a myocardial infarct at autopsy, such cases having been thoroughly studied before death. In practically all of these cases there was a moderate to a marked degree of generalized athero-sclerosis of the coronary arteries in addition to that in the occluded branch. Thrombi were found in 70 per cent of the cases.

They observed that the first results of stoppage of blood supply to a portion of the myocardium was a necrosis of muscle fibres, and to a lesser degree, of the connective tissue fibres and blood vessels. These signs were first recognizable as early as five to six hours after stoppage.

They found that usually there was a thin layer of surviving tissue 0.3 to 0.5 mm. in thickness along the endocardial surface, the infarcts usually occurring in the middle of the ventricular musculature. Polymorphoneuclears were seen to infiltrate quickly the infarcted area. The purpose of their presence was not clear, but it was believed that they produced an enzyme which aided in the breakdown and phagocytosis of muscle fibres.

By the end of the fourth day newly-formed blood capillaries and connective tissue cells were found growing into the infarcted area. By the end of the tenth day the ingrowth of newly formed connective tissue fibres and newly formed blood vessels had become quite marked. The process of this ingrowth started at the periphery and extended centrally. By the end of the second week the muscle fibres were almost completely removed from small infarcts (i.e. 3 to 4 mm. in diameter).

During the third week the removal of muscle fibres was still going on in large infarcts.

The first signs of collagen formation were found in the form of fine collagen fibres. These were first produced by fibroblasts at the periphery.

From the fourth to the sixth week the age of the infarct was largely dependent on the amount of collagen present, and therefore an actual dating was impossible. In conclusion they stated that the rate of healing depended upon the size of the infarct, its location, and the patency of the surrounding arteries. They observed that the rate of healing was slower where there was a diffuse coronary sclerosis (relative anoxemia C.N.H.) than if the other vessels were of normal calibre.

Summary and Conclusions

By this experimental study I have attempted to demonstrate that 100 per cent oxygen therapy can be tolerated by the human being for long hours daily, day after day, without any apparent harmful or deleterious effect, and that its use is valuable in relieving the pain of acute coronary occlusion and the accompanying state of shock and cyanosis.

I cannot, of course, know what, if any, beneficial effects such supplemental oxygen therapy had on the ultimate size of the infarct or on the acceleration of the healing.

According to the studies of Drs. Mallory and White, the ingrowth of new blood vessels appears early, i.e. the fourth day, and is quite marked by the tenth day. Certainly where tissue repair is going on so actively, an abundant supply of oxygen should aid such tissue repair.

The use of 100 per cent oxygen certainly did not harm this patient, and the evidence probably suggests that death was prevented and the healing was accelerated. Certainly the patient was more comfortable as the result of relief of pain and relief from the secondary ill-effects of anoxemia.

Supplemental Notes

Since the presentation of this paper, I have had the opportunity of reviewing studies of Dr. Clark and his associates (*Anatomical Record,* Vol. 50, 1931, page 129) on "The Rate of Ingrowth of New Blood Vessels into Standardized, Transparent Chambers Placed in the Living Rabbit's Ear." Their observations on the rate of ingrowth of new vessels parallels to a remarkable degree the rate of ingrowth of new vessels as observed by Drs. Mallory and White in their study of "The Speed of Healing of Cardiac Infarctions." Therefore it seems that a brief abstract of Dr. Clark's work should be included here.

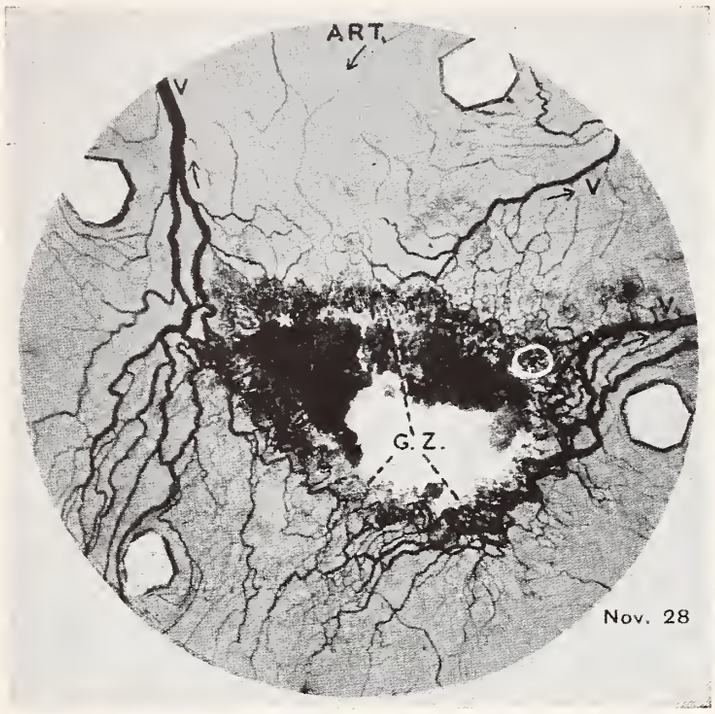

Fig. A. Photomicrograph of the transparent chamber in a living rabbit's ear taken fifteen days after installation and ten days after appearance of new capillaries at the periphery. (From Clark and Clark, Am. Jour. Anat., 55:410, 1934.)

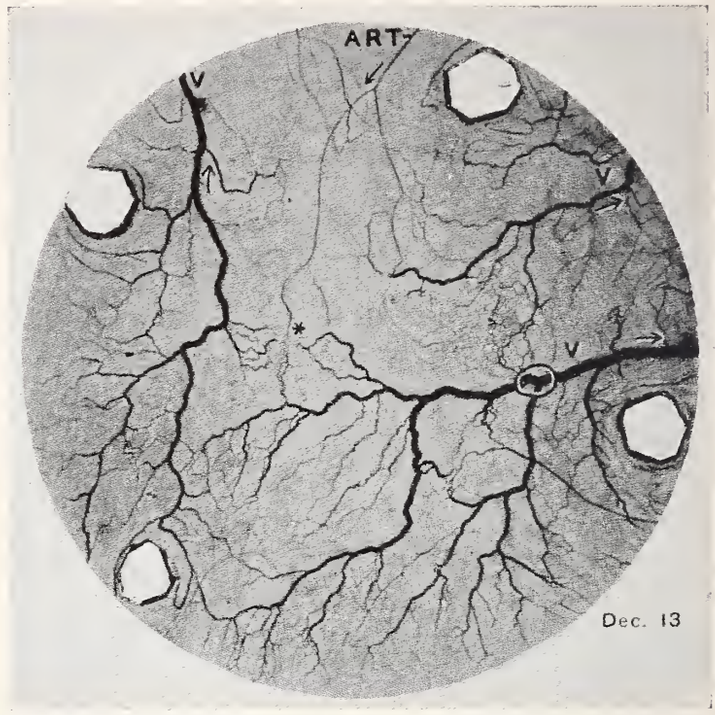

Fig. B. Photomicrograph of the same area as shown in Figure A taken one month after the installation of the transparent chamber. The area is completely vascularized and the vessel pattern has become stable. (From Clark and Clark, Am. Jour. Anat., 55:411, 1934.)

The chambers were so placed in the rabbit's ear that there was a vacant space between the upper and lower tables varying in depth from 40-75 mu. Their observations were based on the placement of sixty standardized chambers and in many instances these chambers were studied daily, and in some instances their observations continued over a period of a year.

They observed that shortly after the installation of the window the vacant space between the tables was filled by blood serum, fibrin, erythrocytes, and leukocytes. Into this amorphous mass new capillaries were first seen to appear at the edge of the chamber between the fifth and ninth days after the installation in some instances, but in the majority the ingrowth of vessels began on the seventh day. These new vessels appeared to arise from pre-existing blood vessels outside the chamber by means of endothelial sprouts which quickly anastomosed to form loops.

The process of sprouting and loop formation continued (Fig. A) until the advancing networks from opposite sides were seen to coalesce, and now the whole space in the transparent window was covered by a vascular plexus (Fig. B). While this advance in the capillary plexus was going on, those vessels at the edge of the chamber which had first appeared, were seen to undergo a differentiation, gradually changing from capillaries into arterioles and venules.

The length of time required for complete vascularization of the window in the rabbit's ear varied in a few instances from sixteen to thirty-five days, but in the majority of cases studied, the vascularization was completed on an average for the entire series, of twenty-three days.

The authors observed that the manner in which new blood vessels grow into the transparent window in the living rabbit's ear corresponds in all essentials to the process of early growth of blood vessels in the embryo, as was shown by the injection studies of Evans ('09) as well as by the studies of Clark ('18) on "The Growth of Living Capillaries in Amphibian Larvæ."

Discussion

Dr. J. A. Lepak, Saint Paul: I think Dr. Hensel should be congratulated on his excellent result. I have used oxygen, like others treating heart disease, for coronary thrombosis. And, as Dr. Hensel recited the findings in his case, I recalled a case in which oxygen therapy was employed for about four weeks. Since the patient objected most strenuously to the mask, the tent was used.

Briefly, in the Spring of 1937 he had an attack of coronary thrombosis. After six weeks he left the hospital and several weeks later he returned to work. In October, 1937, he underwent an operation for an acute empyema of the gallbladder. On the 10th day after the operation, he developed pulmonary embolism involving a large part of the right lower lobe. In three or four months he was quite well again until the fall of 1939 when he had another coronary occlusion, so severe that he went into shock and developed an acute

bilateral hydrothorax. The fluid from the left pleural cavity disappeared shortly, but from the right side it had to be aspirated every seven to ten days for sixteen times for the relief of dyspnea and pain. During this three-month stay in the hospital, it was necessary to give him oxygen most freely. For the first four or five weeks, I do not know of anything that might have given him more relief, especially for pain. Today he is up and about, free of pain, but not free from some fluid in the right pleural cavity.

Recently consulting the Mayo Clinic, he was informed that the fluid in his chest was secondary to his cardiac condition. Despite all measures to eliminate it, it recurs.

This case, however, showed me very forcibly what oxygen can do, and I have no hesitation in commending its use in concentrated dosage over a long period in coronary thrombosis.

The meeting adjourned.

A. G. Schulze, M.D.,
Secretary.

The examination of familial contacts of tuberculin-positive children between the ages of six months and six years, may be a valuable case-finding procedure, since the opportunity for tuberculous infection among very young children is limited to the immediate family circle. FEEDING THE PREMATURE BABY

(Continued from Page 34)

volume by boiling and adding 2 per cent of calcium caseinate (Casec) may have a beneficial effect.

Rectal temperatures should be discontinued with the first sign of diarrhea—the insertion of the thermometer seems to induce bowel movements. Axillary temperature must be resorted to.

Another complication common to prematures is anemia. They tend to develop a low hemoglobin very easily. A hemoglobin determination should be made no later than the fifth week of life, and if low should be repeated weekly. Some form of iron administration should be followed, beginning at the latest by the fifth week of life. Liver extract and/or ferric ammonium citrate with or without copper sulphate have given a very satisfactory response. The infant may receive each day one c.c. of a 10 per cent solution of ferri et ammonii citras for each pound, or 2 c.c. for each kilogram of body weight, and one-half per cent solution of cupri sulphas per pound or one c.c. per kilogram of the body weight. Both preparations are placed in the breast milk or in the feeding formula. The copper is discontinued after a short period of administration and is given for short periods in intervals. Clinical investigations are now in progress in order to determine a more effective method of combating the anemia of premature infants. These studies may lead to further modifications in the type of food and method of feeding of the baby born prematurely.

THE MALMROS-HEDVALL LESIONS OF PULMONARY TUBERCULOSIS IN ADULTS*

A. T. LAIRD, M.D.
Nopeming, Minnesota

THE recent decline in tuberculosis mortality and morbidity and the consequent decrease in tuberculous infection has brought opportunities for studying the beginnings of tuberculosis in the human body that were never before present.

Large numbers of people reach adult life without infection, become primarily infected and eventually develop the adult or re-infection type of pulmonary tuberculosis. This, today, is occurring under our very eyes with the conditions for observation almost as well controlled as they would be in an animal experiment.

The adult or re-infection type of pulmonary tuberculosis is responsible for most of the cases of chronic invalidism or death that result from infection with tubercle bacilli. Only a small percentage of all persons who acquire a primary infection develop this serious form of clinical disease, but when the re-infection type of pulmonary tuberculosis does result, it is always a matter of serious concern and it is extremely important, both from the individual and the public health standpoint, that the diagnosis be made as early as possible.

The presence of this type of the disease may now be determined in certain cases, by the use of the newer methods, long before the patient shows any outward indication of illness or has even a premonition that his health is not perfect.

This has been demonstrated by careful continued studies of large groups of young people who have reached adult life without having been previously infected with tubercle bacilli. Such persons readily acquire a primary infection when exposed to tuberculosis and later a certain proportion of them acquire serious clinical disease in the form of re-infection type of pulmonary tuberculosis.

Opportunities for infection are greater for those studying medicine or nursing, and especially for those who come in close contact with tuberculous patients. A much larger percentage of such students acquire infection. Consequently, a relatively large number of cases of serious progressive pulmonary tuberculosis may be found in such groups. The occurrence of such cases of clinical disease may even be anticipated under such circumstances, and if the entire group is under careful and continuous observation the very earliest manifestations of the illness may be detected.

One interesting study of such a group is that recently reported by Malmros and Hedvall.*

They made systematic examinations of 3,336 students at the University of Lund in Sweden and found 133 cases of definite active tuberculosis.

Their investigations were begun in 1930, and included tuberculin testing, fluoroscopy, the taking of x-rays, and the making of sedimentation tests. Even in the tuberculin negative cases, x-rays were taken as a rule. All cases were checked at least once a year. The cases which became tuberculin positive during the period of observation were checked especially carefully and x-rays were taken of them from two to four times a year, for the following two to four years, even if at first no changes could be found in the lungs. This work could be carried on in this way be-

*Read before the St. Louis County, Minnesota, Medical Society, at Nopeming, Minnesota, May 9, 1940.

*Studien über die Entstehung und Entwicklung der Lungentuberkulose. Published in 1938, Johann Ambrosius Barth, Leipsig.

cause of the fact that special funds were available for x-rays and it was possible to take an unusually large number. In all, more than five thousand were taken, including routine and special films. As a result, a valuable and readily accessible collection was secured for permanent filing and study. In many of the series of x-rays in which at first the findings were normal, Malmros and Hedvall were able to study the beginnings and the later development of the re-infection type of pulmonary tuberculosis.

As already mentioned, 133 cases of definite active cases of adult type tuberculosis were found among the 3,336 students and pupil nurses examined, which makes about 4 per cent of the entire number. Of the 133 cases, sixty-nine were medical students and twenty-four were nurses.

For the purpose of studying the development of tuberculosis in adults, the entire number of cases studied was divided into three groups:

Group I (forty-seven cases).—In this group, those cases of adult type pulmonary tuberculosis were included, which at the beginning of the investigation showed definite negative tuberculin reactions and in which the beginning of tuberculosis and in many cases the entire development into open tuberculosis could be studied.

Group II (forty-three cases).—In this group were included the cases in which the tuberculin test was already positive when the study was begun, but in which a normal chest x-ray was available before tuberculosis developed in the lungs.

Group III (forty-three cases).—In this group, finally, are found the remaining cases, those in which tuberculous infection had already been indicated by a positive tuberculin reaction and by some evidence of tuberculosis in an x-ray of the chest previous to the time when active disease developed.

Group I

Group I is naturally the most important of the three groups since by a study of the forty-seven cases included in it, one can really learn to recognize the changes which occur in primary tuberculous infection and also the later development of the adult type of tuberculosis. Six hundred and four, or approximately 18 per cent of the 3,294 students given the tuberculin test, at first showed negative reactions. Of these 604, the number that changed from negative to positive during the period of observation (1930-1938) was 151, or 25 per cent. Of those whose susceptibility to tuberculin changed in this manner, 104, or about 69 per cent, became positive reactors without ever developing any other signs or symptoms of tuberculosis than the positive tuberculin reaction itself. In the other forty-seven cases (31 per cent) tuberculous changes sooner or later were demonstrated in the lungs. They comprised Group I.

All of these forty-seven patients had had a negative tuberculin reaction and a negative x-ray when first examined. The positive reaction occurred on an average nine and a half months after there had been a negative one; in half the cases in four months and in two cases in two weeks.

Of the forty-seven patients, nineteen developed definite childhood type (primary infection type) tuberculosis of the lungs with the usual primary complex. Six others developed pleurisy only, without a primary complex. Nine others developed various conditions which the authors considered indications of a primary infection including erythema nodosum, phlyctenular conjunctivitis, gland tuberculosis and miliary tuberculosis. Of these thirty-two patients developing primary type tuberculosis, nineteen recovered without further illness during the period of observation, the patient with miliary tuberculosis died, two developed peritoneal tuberculosis, one a marked hilus infiltration, and five of the thirty-two later developed typical re-infection or adult type tuberculosis, one of whom died. Of the entire group of thirty-two patients ill with primary type tuberculosis, twenty-one were hospitalized, and six required pneumothorax treatment.

As will be noted in this group of thirty-two patients who had evident primary tuberculosis, there were five who later developed the re-infection or adult type of pulmonary tuberculosis. Besides them there were fourteen others who developed the adult or re-infection type without having shown any previous evidence of the disease except changing from a negative to a positive reaction.

Altogether nineteen of the forty-seven cases of clinical tuberculosis eventually developed adult type tuberculosis. One died, and five required pneumothorax treatment.

In the cases of primary pulmonary infection in

adults above mentioned, there had been in the majority of cases some general symptoms such as fever, pain in the side and cough. The blood sedimentation rate was usually increased.

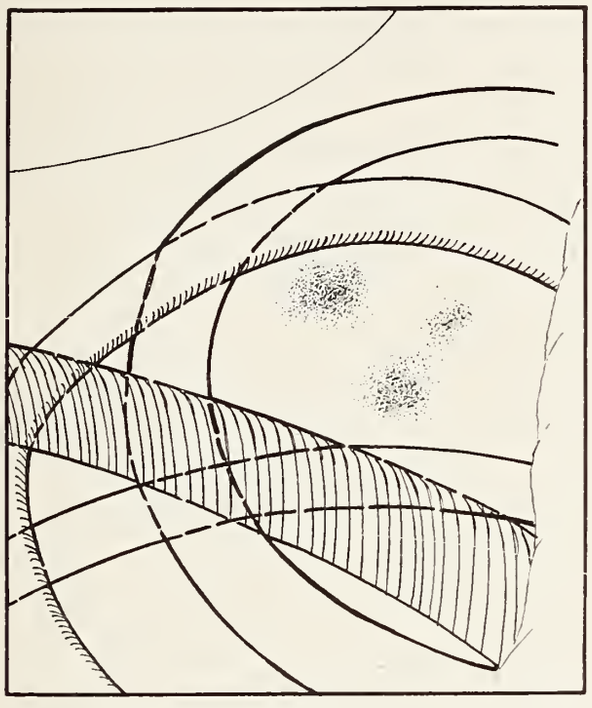

Fig. 1. Subprimary initial lesion. (Diagrammatic sketch by James Wing.)

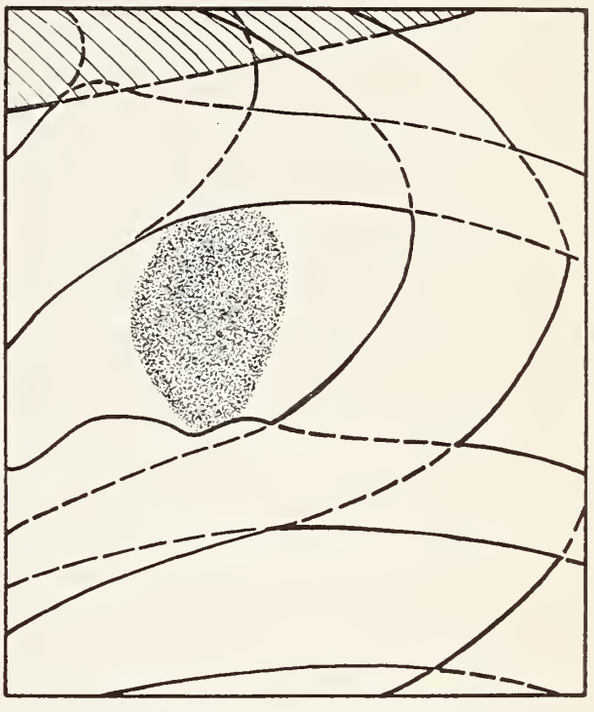

Fig. 2. Early infiltrate. (Diagrammatic sketch by James Wing.)

On the other hand, in the majority of the cases in which the re-infection type of tuberculosis of the lungs developed later, there were *no subjective symptoms of illness* such as had been noted in connection with the primary infection. *Moreover the sedimentation test was normal in most of these cases.*

The re-infection or adult type of pulmonary tuberculosis in those primarily infected in adult life usually began with a lesion called by Malmros and Hedvall a "subprimary initial lesion" which often took the form of single or multiple cloudy spots or flecks on the x-ray film. These in the majority of cases were located in the supraclavicular region or in the first interspace or simultaneously at both places. No special preference for a location below the clavicle could be observed. Assman's teaching that the first lesions of the adult type were usually located below the clavicle was not supported by these findings.

In individual cases an appearance was noted suggesting infiltration, near the area of flecks which the authors designated as "the early infiltrate." Extensive hematogenous dissemination as the first sign of disease was not seen in any case. These "early infiltrate lesions" were denser and their edges more sharply defined than was the case with the "subprimary initial lesions."

These two lesions, the "subprimary initial lesion" and the "early infiltrate," were the first evidences seen of the adult or re-infection type of pulmonary tuberculosis.

Group II

The beginning of the adult or re-infection type of pulmonary tuberculosis was also observed in thirty-seven individuals who at the beginning of the investigation had definite tuberculin reactions but normal x-ray pictures. Six others developed pleurisy and two hilus gland tuberculosis.

The incipient lung tuberculosis in these cases developed in the following forms: in twenty-eight cases larger or smaller "subprimary initial lesions" were demonstrated in the form of somewhat irregular spots or flecks, often fairly sharply defined, but more frequently with edges that faded out and with a tendency to confluence. In one case an isolated "early infiltrate" was present and in one case an isolated cavity in the apex was found.

In this group also, the initial lesions as a rule were supraclavicular or in the first interspace or in both places simultaneously. Here, too, there was found no special tendency for localization in the subclavicular area. In most cases the lesions

showed a progressive tendency in that the process advanced from the apex downward or spread to the opposite lung. In no less than seventeen of the twenty-eight cases showing "subprimary initial lesions," a serious progressive tendency developed later as a result of which cavities developed in ten cases. One of the patients died exactly a year and a half after the "initial lesion" was demonstrated. In two cases the first demonstration of any change from the initial lesion was the appearance of cavities on account of which pneumothorax had to be instituted. The condition in four cases was unstable or slowly progressive. Thirty-six of the forty-three patients in this group were hospitalized; twenty-one received pneumothorax treatment; two died.

The isolated instances of "early infiltrate," which has been shown to be a relatively unusual form of incipient pulmonary tuberculosis of the adult or re-infection type, in the material investigated were located in different sections of the lung; in certain cases they softened and gave rise to cavities, but in others they gradually disappeared by resolution.

A fundamental distinction between these various forms of incipient pulmonary tuberculosis can hardly be made. The designation "early infiltrate" may be used in those cases where the process begins as a larger well limited density.

Extensive hematogenic spreads could be demonstrated by the x-ray in the series only in individual cases and in acute miliary tuberculosis.

Whether the incipient pulmonary tuberculosis began as the smaller flecks ("subprimary initial lesion") or as an "infiltrate" without accompanying areas of flecks, there were in general *no subjective symptoms* nor *any increase of blood sedimentation rate.*

There were forty-three patients in this group in whom definite new lesions of adult type tuberculosis developed. Of these, thirty-seven were hospitalized, eighteen received pneumothorax treatment and three died.

Group III

In the study of these cases, which had all shown some roentgenologic changes during their investigation, there were frequently indications that they had recently developed in new areas the "subprimary initial lesion" which we have described as the commonest form of beginning pulmonary tuberculosis of the adult type, especially when spreading occurred or when new lesions appeared in the opposite and previously normal lung. Such fresh lesions were similar to those already described.

The initial lesion may naturally remain stationary for a long time or even show retrogression. Often there remain traces in the form of sharply contoured, opaque, small flecks, which for some time have been known as Simon's lesions. Exceptionally, the tuberculosis process may light up again from such foci. In some cases there may be little change in a small lesion for several years, after which rapid extension of the disease may occur.

It is of the greatest practical importance not to overlook these early "subprimary initial lesions" or underestimate their importance. They should be anticipated and especially looked for in exposed persons. The lessening cost of chest x-rays will soon make it possible for physicians to have films taken at frequent intervals in all such cases. These should ordinarily be submitted to competent roentgenologists for interpretation. Since evidences of previous primary infection cannot always be demonstrated, it is as Malmros and Hedvall have stated—sometimes impossible to determine positively whether the lesions found are due to primary infection or re-infection.

No pulmonary lesions in adults whether thought to be due to primary infection or to re-infection should be treated casually on the assumption that primary cases have a benign prognosis. The lesions that are evidently due to re-infection are especially uncertain in their course and may cause serious and extensive disease.

The following cases taken from Malmros and Hedvall's report showed the initial lesions of the re-infection type of pulmonary tuberculosis. To them we have added a series of cases observed at Nopeming or in the Duluth hospitals.

Cases in Sweden

Group I

Case 34—Medical student, born 1909.

Mantoux test (1 mg.) negative January 1, 1934, and x-ray of chest negative. Von Pirquet test positive September 21, 1934. Sedimentation test twenty minutes. The patient had recently felt chilly. X-ray showed ill-defined cloudy flecks in the left supraclavicular area. Hilus negative. In a radiograph taken February 21, 1935, the flecks were more marked. The patient was treated at home. At first there was retrogression of the lesion. By March, 1936, there was slight progression on the left side in the supraclavicular area. Ex-

amination of gastric contents showed the presence of tubercle bacilli. For a year the condition was stationary, then further progression occurred on the left in the first interspace, while the changes in the apex were less evident. Now thread-like shadows and flecks appeared which became confluent. The x-ray taken December 12, 1937, showed the flecks for the most part softened into an infiltration in which a central cavity appeared. Sanatorium treatment was given. The patient now feels entirely well.

In this case the "subprimary initial lesions" appeared in the left apex without any demonstrable primary complex, eight months after a negative tuberculin reaction. The case had been under observation four years.

Case 36.—Pupil nurse, born 1914.

Mantoux test negative on June 6, 1934, and x-ray of chest also negative. On February 21, 1938, the Mantoux test was positive. The patient had no symptoms but an x-ray showed apical changes on both sides above the clavicle and in the first interspace, consisting of numerous small, ill-defined flecks. In addition, on the left side there was a cavity (10 x 10 mm.) which showed much larger on the x-ray taken on May 5, 1936. Accordingly the left lung was collapsed by pneumothorax. Later there was extension of the lesions on the right side which necessitated sanatorium treatment and pneumothorax treatment on the right side. Tuberculosis of the peritoneum developed later.

The "subprimary initial lesions" with cavitation developed in this case in the apex and upper lung areas about a year and a half after a negative tuberculin test. About ten months later, peritoneal tuberculosis developed. There was no demonstrable primary complex. The case was under observation three and one-fourth years.

Nopeming Cases

Group I

Case 18859 (St. Luke's No. 11701). F., aged nineteen (1936), student nurse. No tuberculosis in family. Mantoux test negative in 1936 and 1937. Stereoscopic lung radiograph June 4, 1936—negative. Lung radiograph April 28, 1937—negative. The patient worked on tuberculosis service in January and February, 1938.

Radiograph taken January 19, 1938, revealed a small area in the right apex at the junction of the upper margins of the clavicle and first rib. This was a spot or fleck about 1 cm. in diameter together with delicate streaks and mottled areas. Stereoscopic radiograph January 20, 1938, revealed the lesion more clearly. The patient had no symptoms. Radiograph taken October 5, 1938, rather unsatisfactory but was interpreted as negative.

Radiograph May 26, 1939, revealed an infiltration extending downward from the original lesion into the first and second interspace, consisting of soft streaks and mottled areas. The patient was asymptomatic. Radiograph June 3, 1939, showed no change. Radiograph July 7, 1939—slight change. The patient graduated in June, 1939, and worked until January, 1940, when she had hemorrhages.

Stereoscopic radiographs January 9, 1940, revealed slight contraction of the lesion with a hazy infiltration at the second right interspace. The patient was hospitalized and pneumothorax was induced on the right side. Tubercle bacilli have not been demonstrated.

Group II

Case 1625E (986 O.P.).—F., aged twenty-three (1932), graduate nurse employed at the sanatorium. Mantoux test was positive at the beginning of employment. Radiographs were taken at this time. Those taken on December 19, 1929, October 15, 1931, and November 25, 1932, were negative except for a calcified Ghon tubercle near the right cardiophrenic angle.

Routine radiograph November 28, 1933, revealed a minimal involvement in the left lung consisting of "flecks" at the level of the second rib and second interspace. The patient had no symptoms. She remained on duty. Radiographs taken July 8, 1934, and December 30, 1934, showed contraction of the lesion which now appeared as fine streaking at the second interspace. In April, 1935, the patient complained of a slight dry cough and weight loss.

On April 13, 1935, radiograph now revealed an increase in the lesion consisting of a cloudy infiltration in the first and second interspaces. The patient was hospitalized and rapidly lost symptoms. She was unable to raise sputum. Radiographs taken May 16, 1935, and June 1, 1935, showed rapid clearing. The patient was allowed to go home for rest and returned to duty September 1, 1935.

On October 3, 1935, radiograph revealed a fairly fibroid lesion as residue. Frequent radiographs to date have shown slow contraction of the lesion.

Radiograph taken January 1, 1940, shows the present status of the lesion, which does not appear to be active.

Group III

Case 2286.—M., student, aged twenty (1933).

The mother had tuberculosis with positive sputum. The patient was in excellent health, and played on college football, basketball and hockey teams.

Radiograph taken April 9, 1933, revealed calcified glands and a Ghon tubercle in the left lung. In the first and second interspaces on the right there were scattered "fleck-like" areas. The patient had no symptoms but was reëxamined May 7, 1933, and June 5, 1933.

On June 5, 1933, radiograph showed conglomeration of the mottling with a spot of increased density 1.5 cm. in diameter at the second right interspace. The left lung was unchanged. The patient was advised to enter a sanatorium but refused and continued school work. There were no symptoms. He did not return for further examinations until December.

Radiograph taken December 17, 1933, revealed increase in the lesion with a cavity at the second right interspace 1.5 cm. in diameter. The patient complained

of a cold, but refused treatment. Radiograph January 17, 1934, showed very little change

The patient's condition was again checked by x-ray March 3, 1934, which now revealed a marked atelectatic or pneumonic area involving the lower half of the upper lobe. Cavity was patent. The patient had very slight symptoms. Sputum was positive.

Pneumothorax was induced March 17, 1933, with good collapse. The patient was discharged with pneumothorax June 30, 1934. The lung was reëxpanded in November, 1936. The patient's last check-up, August 21, 1938, showed a fibroid and calcified area in the region of the original disease, apparently not active. Recent report (1940) is that he is in excellent health.

THE VOLLMER PATCH TEST AND THE MANTOUX TEST

F. M. FELDMAN, M.D., Dr.P.H.,*
Rochester, Minnesota
in collaboration with
A. F. RISSER, M.D., and E. R. SCHWARTZ, M.D.
Stewartville, Minnesota

IN 1937, Vollmer and Goldberger[9] first reported on the patch test used in this survey. In the 209 cases they tested, the patch and Pirquet tests were in conformity in 89 per cent. No Mantoux tests were done. In 15 cases the patch was positive and the Pirquet negative, and in 7 the reverse was true.

Taylor[7] tested a group of nurses, medical, law, and engineering students using the Vollmer patch and 0.1 mg. O.T. Mantoux tests. Of the 744 tested, 511 were negative to both tests, 191 positive to both, 27 positive to the patch test and negative to the Mantoux, and 15 negative to the patch test and positive to the Mantoux. He concluded that the patch test was as effective as the Mantoux with 0.1 mg. O.T.

In 880 tests on school children, Peck and Wegman[5] were able to obtain only ninety-four positive patch tests on the 319 individuals who had reacted to Mantoux tests done with first and second strengths purified protein derivative (P.P.D.).

Weiner and Neustadt[11] using a different approach gave Mantoux tests with 1:1,000 O.T. only to those who reacted negatively to either or both the patch and Pirquet tests. Only 3 of 60 reacting negatively to the patch and Pirquet tests reacted to the Mantoux. Of the 10 positive to the patch only, 7 reacted to the Mantoux. And of the 3 positive to the Pirquet only, one reacted to the Mantoux.

Vollmer and Goldberger[10] gave patch tests and Mantoux tests with 0.1 mg. O.T. simultaneously to 417 children on a general pediatric service. In this group 28 were positive to both tests and 385 negative to both tests. The tests disagreed or were questionable in only 4 cases.

Court[1] reported 100 per cent correlation between the Mantoux with 0.1 mg. O.T. and the patch test in 110 children, but Mantoux tests were read as negative if the induration was less than 10 mm. in diameter.

In testing 91 tuberculous children and 5 adults at a sanatorium, Steward[6] observed 90 reactions to both the patch and 0.1 mg. O.T. Mantoux, 6 reactions to the patch test alone, and none to the Mantoux test alone.

Of 536 children tested by Hart,[2] 436 had negative reactions to the Vollmer test patch and a Mantoux test with 0.01 mg. O.T., and 97 had a positive test to both. In only 3 instances was there disagreement.

Hughes[3] found that of 78 children positive to the Mantoux with first strength P.P.D., all were positive to the patch test. And of 22 positive only to second strength P.P.D., 11 had a positive patch test.

Of 712 children tested by Pearse, Fried, and Glover,[4] 492 were negative to the Mantoux test using first and second strengths P.P.D. and the patch test, 35 were positive to both, 67 were positive to the patch test alone, and 21 to the Mantoux test alone. In this study the patch test gave 7 per cent more positives than the Mantoux.

All investigators agree that the patch test has certain definite advantages in that it is painless, involves no instruments or sterilization, and never leads to a severe local or general reaction. Furthermore, the test material keeps its potency for months.

During the first part of April, 1940, Mantoux

*Director, District No. 3, Minnesota Department of Health.

tests and tuberculin patch tests (Vollmer) were given simultaneously to approximately 300 students, teachers, and employes of the schools at Stewartville, Minnesota. Although the number of tests here reported is too small for any definite conclusions to be reached, such experience may be of value when added to that of other investigators.

For the Mantoux tests, 0.1 c.c. of 1:1,000 O.T. was injected intracutaneously on the anterior surface of the right forearm. The tuberculin was obtained from the Division of Preventable Diseases, Minnesota Department of Health.

The patch tests were applied to the right or left of the spine in the scapular region after the skin had been cleansed with acetone. The patch test material was purchased on the open market and was manufactured by the Lederle Co.

The Mantoux tests were read at the end of 48 hours and the patches were removed at that time. The patch tests were read at the end of another 72 hours rather than 48 hours because of an intervening Sunday, and it is possible some of the weaker reactions may have faded over this time. X-ray plates of all reactors were made at the Mayo Clinic, Rochester.

As is evident from Table I, the patch test was negative in all 16 persons having a one plus Mantoux reation, and on three of the four with a two plus Mantoux reaction. All of those with three plus Mantoux readings, however, had definite patch test reactions. Only three persons had a positive patch test with a negative Mantoux.

TABLE I. TUBERCULIN TEST RESULTS BY AGE

Mantoux Test	Neg.		1+		2+		3+

Totals	3	0	0	15	1	3	9	0	31

It would appear that the patch test is unreliable for indicating tuberculin sensitivity below the level which will produce a three plus Mantoux reaction with 0.1 mg. O.T.

In Table II, x-ray findings have been correlated with the tuberculin test results. Although some of the Mantoux tests read as one plus were doubtful positives, this table reveals that eight had definite x-ray evidence of infection. It should also be noted that all three with negative patch tests and two-plus Mantoux tests had x-ray signs of primary tuberculosis.

Tuberculin tests, especially in surveys of this nature, are used primarily as a screen to indicate individuals most likely to exhibit open active tuberculosis on further examination. In this instance, no active cases were found, and in most studies reviewed no mention was made of the relative effectiveness of the Mantoux test and the patch test in this respect, although Vollmer[8] did state in a popular article that of 847 children admitted to Mt. Sinæ Hospital, there was only one case with clinical, roentgenographical, or bacteriological findings indicating a tuberculous infection that failed to react to the patch test. This was a child with miliary tuberculosis in whom the Mantoux test with 1.0 mg. O.T. was also negative. In this article he also reported a mass examination of 613 high school students carried out by the New York Health Department with the Mantoux, patch test, and x-ray examinations in which no significant lesions were missed if the patients failed to react positively to either the patch or Mantoux test.

It may be that the patch test will prove to be practical even if those with slight sensitivity to tuberculin are missed. Before this question can be answered, further study of survey end results seems indicated.

PNEUMONIA IN RURAL COMMUNITIES*

R. V. WILLIAMS, M.D.
Rushford, Minnesota

THE purpose of this paper is not to bring out statistics of a large group of pneumonia cases, but rather to illustrate the marked changes in the treatment of pneumonia which have taken place the last thirty-six years in rural communities in Minnesota.

In the early days of my practice in Rushford, a small city in southeastern Minnesota, more than thirty-six years ago, pneumonia was dreaded more than any other disease, and from early cold weather until late in March, it was the most frequent of all serious illnesses. Calling the doctor was usually delayed by people in the country until the patient had been sick for several days. He was called earlier only when a patient began expectorating a pink colored sputum, or if there were chest pains with a cough. These symptoms were interpreted, then as now, by some member of the family or some neighbor as pneumonia, and it was frequently called "Ammonia on the Lungs." A few of you older men present today will remember the helplessness of the situation. The word "Pneumonia" or "Lung Fever," spread fear into the hearts of the whole household. Moving a patient to a hospital was out of the question. Those were the horse and buggy days. Nurses were few and far between, they were considered more or less of a luxury, and when needed were seldom available. The care of the

*Read before the annual meeting of the Southern Minnesota Medical Association, Red Wing, Minnesota, September 23, 1940.

patient was left to members of the family or perhaps some "handy woman in the neighborhood." She usually had a solemn face and often the only order she would and could willingly carry out would be the application of a mustard plaster to some painful part of the chest, or to the side of the chest involved. Orders for sponging or the giving of a general bath to make the patient more comfortable or for the reducing of temperatures were looked upon with horror. Fresh air and baths were considered dangerous for pneumonias, and furthermore the windows had been fastened shut for the winter. Drugs were used in the hope that they would have some value, and the worst tasting mixture was usually given credit for being a very good "Pneumonia Medicine." Quinine was used consistently, and if large enough doses were given it was probably the most valuable drug used. Whiskey was kept handy and in cases in which the pneumonia was terminated by a crisis it was very valuable. In other cases it helped the night watch keep up their courage. Mortality ranged from 15 to 20 per cent throughout Minnesota.

Very little progress was made in the treatment of pneumonia for many years. Better roads and automobile transportation of pneumonia patients to hospitals made some changes for the local practitioner and the patient had better care, but mortality rates were still high. Oxygen undoubtedly tided over a few, provided it was used early and not merely as a last resort, and the most that can be said for oxygen is that it is a sustaining agent and makes the patient more comfortable. Optochin Base, an alkaloid of the cinchona family, was without any doubt in my mind the best anti-pneumococcic drug until the present sulfanilamides came into use. I used it for many years and had more confidence in it than in any other drug, until its dangerous effects on the retina were reported and even blindness followed its use in a very small percentage of cases. Fortunately I had no such accidents. So much for reminiscing.

During a period of fourteen months beginning in February, 1939, and ending in April, 1940, I treated thirty-one patients with pneumonia. For seventeen of these I had the pneumonia typed. The other fourteen had been sick for more than three days before I was called and at that time I could see no very good reason for typing, as far as the treatment with serum was concerned. If I had to do it over again, I would have them all typed. I will come to this question a little later.

The distribution of types was as follows:

No. Patients	Types
2	3
1	4
4	7
2	8
1	9
2	13
1	16
1	17
1	19
1	23
1	32

In eleven of the seventeen cases in which I had the sputum typed I used the anti-pneumococcus serum; in four of these I gave a total of 80,000 units and in seven I gave a total of 60,000 units. In all cases, rabbit serum was used and there was not the slightest reaction in any of the cases. The conjunctival test with rabbit serum was used in all cases in which serum was administered.

In the other six cases that were typed, forty-eight hours had elapsed before I got a report, due to difficulty in typing, and I felt that the time had passed when the greatest amount of good could come from serum administration.

The Minnesota State Board of Health laboratories did the typing in each case, and they give a splendid service twenty-four hours each day, and the only problem in rural communities is to get the sputum specimens to the laboratories with as much speed as possible. Rushford, like many other small towns, is not blessed with too many mail trains, but we have a good highway across to Winona—twenty-one miles away, where there are many fast mail trains, plus bus service. In order to get a report back in a hurry the specimens were either taken to Winona by some member of the patient's family or I had them taken over by messenger and sent special delivery. In a number of cases the report as to type was telephoned to me eight hours from the time the sputum was sent from Rushford to Winona. In the telephone report coming from the laboratory the question was always asked if I wanted serum, and in a number of cases the serum was called for at the bus depot in Winona and brought back and given to the patient within eighteen hours

from the time the sputum was sent to the laboratories.

Getting back now to the fourteen cases I didn't have typed: One of these patients died, the only certificate of death by pneumonia I signed during the fourteen months. The patient was a woman eighty-three years old who had been sick several days before I was called. She didn't take kindly to sulfapyridine and began vomiting following the third dose. I then gave it rectally in solution and, of course, most of it in suspension but it didn't do anything for her. Given this way there is probably very little absorption. Whether she would have survived if her pneumonia had been typed and serum given is a question. In cases like this I believe pneumonia should be typed, for then all the treatment of today could be applied.

The other thirteen patients ranged from two years to seventy-two years and all of them had been sick for more than three days before I saw them. Three of them were brought to the office, including a brother and sister—fourteen and sixteen years old—who had temperatures of over 103 degrees. They were brought in a distance of over nine miles over bad roads. The sister had a stormy time, delayed resolution with an irregular temperature that lasted for more than three weeks. These patients undoubtedly had the same type of pneumococcic infection, but the brother got along very well. The length of his illness was the average; resolution took place normally. Both of them had the same treatment with sulfapyridine. The question in my mind has been, would the sister have had a normal recovery without so much loss of time if she had had the help of serum?

All of the thirty-one patients were given sulfapyridine, and there can be no question as to its value—it has changed the picture of the treatment of pneumonia, provided the patient can tolerate the drug. Four of my patients could not. One of the patients who could not tolerate sulfapyridine was a robust farmer fifty-seven years old who had a type 3 infection. He started to vomit following the second dose and no matter how it was given or with what it was given it seemed like poison to him. His temperature was 104.5 degrees and the greater part of the right lung was involved. Fortunately there was no delay in getting the sputum typed and the first dose of the serum was given to him in eighteen hours from the first time I saw him. He was given 20,000 units every twelve hours for four doses. He responded to this treatment beyond expectations and his temperature dropped to normal a few hours following the third dose. From this time on he made an uneventful recovery.

Only one of the thirty-one patients had a complication and that was a pleural effusion of 36 ounces of a clear fluid. Five of the thirty-one had the care of a trained nurse, three of them full time, the other two part time. All the others were taken care of by members of the family who were given instructions as to general care, keeping a memorandum of temperature readings and the intake of fluids, especially the juice of citrus fruits.

Conclusions

1. Typing should be done in all cases of pneumonia and can be done in all rural communities even though the doctor is not called within twenty-four or thirty-six hours following the onset. It will to some extent give us a clue as to the virulence of the type of pneumonia we are dealing with.

2. The administration of anti-pneumococcic serum according to type is the logical treatment, and even though it is not 100 per cent effective, it can be given with the assurance of some benefit, and in the treatment of pneumonia we need every help possible.

3. Sulfapyridine, if given carefully and judiciously, is without any question the most valuable drug discovered to date for the treatment of pneumonia, provided the patient can tolerate the drug.

4. Pneumonia cases can be typed with speed, and treated with efficiency in rural communities, by country doctors in spite of and without the benediction of Hugh Cabot, who has belittled the value of "country doctors."

CARCINOMA OF THE STOMACH*

JAMES T. PRIESTLEY, M.D.
Rochester, Minnesota

CARCINOMA of the stomach is a lesion which occurs so frequently and which has such grave implications that it should be of interest to all engaged in the practice of medicine and surgery. It has been estimated that approximately 40,000 people die each year in this country alone of carcinoma of the stomach. In a recent report by Livingston and Pack it was stated that in this country carcinoma of the stomach accounted for more deaths than traffic accidents between the years 1923 and 1937. There is some evidence to suggest that malignant gastric lesions are accounting for more deaths each year.

At the present time the only chance to cure carcinoma of the stomach resides in recognition of the disease early enough to permit its surgical removal. Furthermore, from present knowledge the only hope of reducing mortality from this lesion in the future is by establishing the diagnosis early in a higher percentage of cases, so that resection will be feasible in a greater number of cases. Since Billroth's first successful resection for carcinoma of the stomach, performed fifty-eight years ago, many patients have been cured by this means of treatment, but, so far as I know, no patient has been cured by any other form of treatment.

How then is the early diagnosis of carcinoma of the stomach to be established: Fortunately, the means by which this may be accomplished when the opportunity is presented are within the reach of us all. The necessary prerequisites include: (1) a clear appreciation of the early symptoms which may be caused by carcinoma of the stomach, (2) the accurate evaluation of a carefully elicited history, (3) possession of a readily aroused suspicion concerning the possibility of carcinoma of the stomach, and (4) the insistence on a competent roentgenologic examination of the stomach in every possible case. If we wish to establish the diagnosis early in the course of the disease one of the first things we must do is to discard the old textbook picture of carcinoma of the stomach. The symptom complex of gastric carcinoma described in most textbooks includes only the findings of long-standing and advanced lesions. The characteristics of this disease usually mentioned consist of emaciation, palpable tumor, nodules in the liver, and also anemia, cachexia and loss of strength. Obviously, if we wait until this stage of the disease is reached, the patient benefits very little by its recognition.

Several years ago Wilbur described three clinical syndromes, one of which occurs usually in the presence of carcinoma of the stomach. I believe that these syndromes are worthy of emphasis as their recognition is essential in detecting early gastric carcinoma. The first of these is a so-called typical history usually presented by a patient of middle age or older. (It is well to remember that in 8 per cent of cases, gastric carcinoma affects patients forty years of age or less.) Commonly the patient has enjoyed perfect digestion until the rapid onset of dyspepsia. This dyspepsia may consist of anorexia, discomfort after meals, belching, epigastric distress, nausea, and occasionally vomiting. These symptoms usually are progressive and constant in nature, and as time goes on there is loss of weight and strength. A history of this type always should arouse the suspicion of gastric carcinoma and always should demand careful roentgenologic examination of the stomach. A second group of patients presents the so-called ulcer type of history. The patient who presents this type of history may have experienced symptoms similar to those caused by peptic ulcer for a brief or prolonged time. Very frequently these symptoms may then change in one of various ways. There may be disappearance of the customary intermittency of symptoms or alteration of the pain-food-ease sequence so commonly present in cases of uncomplicated peptic ulcer. Food may aggravate rather than relieve the distress and a more or less continuous dull ache may develop in the epigastrium. Nausea and anorexia occur frequently and the ordinary measures which gave relief previously may fail to do so now. The

*From the Division of Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the annual meeting of the Southern Minnesota Medical Association, Red Wing, Minnesota, September 23, 1940.

possibility that a patient who actually has carcinoma of the stomach may present symptoms suggestive only of benign ulcer renders roentgenologic examination of the stomach imperative before instituting medical treatment in any case of suspected peptic ulcer. A third group of patients with gastric carcinoma may present a "nondescript" type of history. In this group the symptoms referable to the gastro-intestinal tract may be vague, indefinite or entirely absent. They may consist of constipation, bloating, belching, abdominal discomfort or other similar nonlocalizing, rather mild, complaints. Not infrequently the patients may say that they were in perfect health until the occurrence of a recent infectious process such as "flu," and that they have not regained their strength. There may be a gradual loss of weight and strength and the development of anemia. It may be difficult or virtually impossible to establish the diagnosis early in cases in which patients present this symptom complex. From such an individual even the most astute clinician may elicit no evidence suggestive of gastric carcinoma until the lesion is well advanced. It is unfortunate but true that certain carcinomas situated in the stomach make their presence known only after the hope of surgical cure has passed. This fact, rather than being discouraging, however, should make us more on the alert to recognize all those lesions which can be detected while they are still amenable to surgical treatment.

A clear appreciation of these three groups of symptoms which may be experienced by patients with gastric carcinoma is most important in the early recognition of this disease. One of these three definite syndromes may not be present always and various combinations may occur; however, any of these symptoms always should arouse suspicion of the possibility of gastric carcinoma and demand roentgenologic examination. In order not to overlook certain instances of carcinoma it is necessary to perform many roentgenologic examinations of the stomach which reveal only normal findings. This is a matter of small concern, however, considering the benefits that may accrue in cases in which early diagnosis of gastric carcinoma is established.

What then are the factors which lead to the late diagnosis of carcinoma of the stomach? These may be divided into several categories. One of the most important factors remains inherent in the nature of the lesion itself. Unfortunately, carcinoma of the stomach may be so situated and develop in such a manner that it does not cause symptoms early in the course of its growth. When the growth arises in the cardia or fundus, recognizable symptoms may be produced only after extension or metastasis has rendered the condition inoperable. There seems to be little or nothing that can be done to overcome this obstacle to early diagnosis. The second factor which may lead to late diagnosis resides largely with the patient because of his failure to seek medical attention promptly following the onset of symptoms. The mild and apparently innocuous nature of the symptoms may mask the seriousness of the underlying lesion. Another cause of growing importance is the use of various home remedies and, more particularly, self-treatment as directed by the producers of certain patent remedies. As regards this "patient" factor which leads to late diagnosis of carcinoma of the stomach in a certain percentage of cases, something can, of course, be accomplished by intensified educational programs for the laity.

The third factor which leads to late diagnosis of carcinoma of the stomach in some cases resides with the medical profession in failure to recognize the condition early when the opportunity for diagnosis is presented. What leads to this failure on our part? There are, of course, numerous reasons. Unfamiliarity with the clinical picture which is presented by many patients having early carcinoma of the stomach may be responsible in some cases. Reluctance to secure roentgenologic examination because of expense or local unavailability of adequate roentgenologic facilities not infrequently results in a postponed diagnosis. If diagnosis is to be made while the lesion is still curable roentgenologic examination must be carried out, in many cases, when perhaps the lesion is suspected only faintly and not after the clinical diagnosis is obvious.

In addition, there are certain pitfalls in the diagnosis of carcinoma of the stomach against which we should be on guard. First and foremost probably is that of gastric ulcer. Whether a benign gastric ulcer may become malignant will not be discussed at this time; however, the fact remains that certain patients who actually have a small ulcerating carcinoma of the stomach may be thought to have a simple benign gastric ulcer.

Our responsibility, therefore, after establishing the diagnosis of gastric ulcer if operation is not performed at this time includes careful observation, both clinical and roentgenologic, in order to be certain that the ulcer disappears entirely, as anything short of this is not evidence that the lesion is benign. Furthermore, the patient should be followed over a period of time in order to be certain that recurrence does not take place. In certain cases a diagnosis simply of anemia may be made and the underlying cause of the anemia such as carcinoma of the stomach or a malignant lesion elsewhere in the gastro-intestinal tract may remain undetected. For this reason roentgenologic examination of the stomach and in fact the entire gastro-intestinal tract should be performed in every case of severe anemia of indeterminate cause. At times a gastric polyp may be or become malignant, and when a polyp is found in the course of roentgenologic examination of the stomach it should not be disregarded merely because it does not appear to be responsible for the patient's symptoms. In most cases such polyps probably should be removed, but if such a polyp is not removed surgically it should be observed by a competent roentgenologist periodically in the future and operation performed if there is any growth or other change in its physical characteristics. The fourth group of patients in whom carcinoma of the stomach may not be recognized early is represented by the individual of middle-age or beyond who comes to the physician with obvious organic disease, the exact nature of which cannot be determined. The patient usually is anemic, has lost weight and is weak; yet, all methods of clinical investigation including roentgenologic and perhaps even gastroscopic examination reveal only normal findings. We should insist that this individual return for reëxamination in two or three months, as at that time a growth in the stomach may be detected. If the patient is left to his own devices and not impressed with the importance of reëxamination in the near future, he may return six or twelve months later with a carcinoma of the stomach which is grossly inoperable.

What are the prospects of cure for the patient who has carcinoma of the stomach? When these prospects are considered from the point of view of all cases in which the diagnosis has been made, the outlook is rather gloomy; however, when one considers the prognosis of those who have had the benefit of gastric resection, the chance of cure is far more favorable. Considering first all cases in which the diagnosis is made, experience at the present time at the Mayo Clinic reveals that surgical exploration is performed in approximately sixty of each 100 cases, and in the remaining forty, palliative medical treatment alone is instituted because of the advanced and obviously inoperable nature of the lesion. Of these sixty cases in which exploration is performed, resection of the stomach is performed in approximately thirty. Postoperative mortality will account for approximately five of these thirty patients. This means, in other words, that in only approximately twenty-five of the original 100 cases in which the diagnosis was made will the patients have a chance for cure and only about one-third of these will live for five years. Obviously, if diagnosis were established earlier in a higher percentage of cases, surgical removal of the lesion could be accomplished more frequently and consequently the number of cures increased.

If we consider the prospects of cure only from the point of view of those who have undergone gastric resection and survived the operation, the outlook is more favorable. In a recent study of 10,890 cases in which gastric carcinoma was diagnosed at the Clinic in the years 1907 to 1938, inclusive, it was found that of the 1,951 patients who survived gastric resection and were traced, 29 per cent lived for five years or longer following operation. There are, of course, many factors which influence the prognosis when gastric resection has been performed. The three most important factors are: (1) grade of the lesion, (2) local extent of the lesion, and (3) the presence or absence of involvement of the regional lymph nodes.

Summary

It should be emphasized that carcinoma of the stomach occurs very frequently, probably more frequently than we are inclined to realize. At present the only hope for cure of carcinoma of the stomach resides in surgical removal of the growth. The only hope of removing a carcinoma of the stomach surgically resides in establishment of the diagnosis sufficiently early. The means for establishing the diagnosis of carcinoma of the stomach early are within reach of us all,

namely: appreciation of the early symptom-complex of this lesion, a carefully elicited history, an easily aroused suspicion of gastric carcinoma, and the insistence on roentgenologic examination by a competent specialist in this field in any case in which the presence of a malignant lesion is faintly suspected. Of patients who survived gastric resection, 29 per cent were alive five years after operation.

PROGNOSIS FOLLOWING PALLIATIVE RESECTION FOR CARCINOMA OF THE SIGMOID*

CHARLES W. MAYO, M.D.,
and
JOSEPH M. MILLER, M.D.
Rochester, Minnesota

UNFORTUNATELY, as yet in the therapeutic attack on carcinoma of the colon, sufficient progress has not been made in either the medical education of the public or the diagnostic acuity of the physician. Accordingly, many patients suffering from such malignancies find that their condition is in an advanced stage when they are first subjected to operative procedures. It is inevitable that surgeons interested in patients who have colonic neoplasms frequently will find, on opening the abdomen, a carcinoma which is inoperable, so far as cure is concerned, either because of the local situation or because metastases are present in the liver. Such a situation is perplexing for the surgeon inasmuch as the prognosis is so hopeless. The local growth may be of the small annular variety, and nearly every surgeon can recall a case either in his own practice or in that of a colleague, in which resection of such a malignant lesion, even when metastasis is present, is followed by a considerable period of well-being on the part of the patient, during which time the patient actually may gain in weight and strength.

Because luminal obstruction of the intestine is or will be present if the patient has carcinoma of the colon, the surgeon must act in some manner to circumvent the discomforts attendant on such a catastrophe. Action must be taken even though a cure may not be achieved.

When the lesion is situated in the right half of the colon, ileotransverse colostomy will short-circuit the obstructed region and will solve the difficulty so far as obstruction is concerned. When the transverse, descending or sigmoid segments of the bowel are involved, the tumor-bearing portion often may be exteriorized and removed. Occasionally, in the splenic flexure and descending colon, when there is redundancy in the transverse and sigmoid portions of the colon, colocolostomy may be accomplished. Still more rarely, sigmoidosigmoidostomy, rather than resection, may be the procedure of choice. Colostomy, on the other hand, usually is the procedure of choice for inoperable rectosigmoid and rectal lesions.

Statistical studies pertaining to the duration of life of patients following palliative resection for carcinoma in any segment of the colon are not numerous. Gabriel and Lloyd-Davies, discussing the performance of colostomy for inoperable carcinoma of the rectum, presented an interesting analysis. Two hundred and thirty-eight patients having locally inoperable cancer were subjected to colostomy and more than 50 per cent died within twelve months after this operation. Metastases to the liver and peritoneum were present in a group of sixty-eight patients subjected to colostomy and, as might well be predicted, more than 50 per cent of the patients were dead within six months of the performance of this operation.

Colocolostomy may be done if the malignancy is situated in a favorable site. However, the procedure is not safe in the presence of more than a mild degree of obstruction. The advantage

*From the Division of Surgery, The Mayo Clinic (Mayo) and The Mayo Foundation (Miller—Fellow in Surgery), Rochester, Minnesota.

of avoiding creation of an abdominal anus is readily apparent in cases in which colocolostomy can be performed. Wilson and one of us (Mayo), previously have reported the results of palliative colocolostomy performed in forty-two cases of inoperable malignant tumors of the colon. Significant features of this review were the facts that the primary operative mortality was 14 per cent and that five of the six deaths occurred in cases in which the transverse colon was anastomosed to the sigmoid segment. Increased tension on the line of anastomosis and leakage may have accounted for these deaths; for this reason preliminary cecostomy may be called for in such circumstances. Among the thirty-six patients who survived the operation, the average duration of life was 11.5 months.

The advantages of simple colostomy done above the tumor-bearing portion of bowel are apparent. Intestinal obstruction is prevented or relieved, abdominal pain is alleviated and the danger of hemorrhage is lessened. In addition, patients who have rectal carcinoma report a decrease in discharge and mitigation of tenesmus, both of which results are particularly appreciated. Many individuals have a temporary abatement from the cachectic syndrome, frequently associated with inoperable carcinoma. Appetite, weight and strength are enhanced for a variable period, although the end result is forecast at the time of surgical therapy. However, a brief and often happy respite from their difficulties is afforded these unfortunate individuals.

In the treatment of patients who have small lesions which can be removed without technical difficulty, the primary growth often may be resected to the advantage of the patient. Although statistically unproved, it is the feeling of many surgeons that, even when demonstrable metastasis of small degree is present in the liver, the secondary lesions do not develop as rapidly when the stimulating influence of the preliminary tumor has been removed as they would were the primary lesion undisturbed. With these thoughts in mind, we studied a group of patients for whom palliative resections of various types for carcinoma of the sigmoid had been employed. These patients comprised an admirable group for study in that not only was the obstruction relieved by the operation, but in addition, the primary growth was removed. Some comparisons also may be made between members of this group and those patients subjected to colocolostomy referred to previously.

Fifty-five patients comprised the group for whom palliative resection for carcinoma of the sigmoid was performed. Included in this number were thirty-nine men and sixteen women, and as might well be expected, 82 per cent of the patients were between the ages of forty and seventy years. As further evidence of the risk of operation for these patients, it might be added that 38 per cent were in the sixth decade and 29 per cent were in the seventh decade of life. Only four of these people had malignant lesions which were considered to be locally inoperable in relation to eventual cure. The remainder of the group had nodules in the liver or peritoneal metastases.

By far the majority of these patients were subjected to the Paul-Mikulicz procedure of exteriorization of a portion of bowel or modification of this operation into extraperitoneal resection. In proceeding according to the latter technic, the growth is removed by cautery over a three-bladed clamp after the abdominal wall has been closed in layers. In some instances a catheter was slipped into the proximal loop of bowel to permit passage of gas and fecal material without contamination of the operative wound. Since the catheter remained in place for a period of five to eight days, sufficient progress in healing of the wound took place to prevent infection.

Ten of the fifty-five patients succumbed to the operative procedure, resulting in a primary surgical mortality of 18 per cent. An additional ten patients are still alive at the time of writing. The postoperative duration of life for the remaining thirty-five patients was 16.5 months. Because of the small number of patients, making of a correlation between the pathologic grade of the tumor and longevity did not seem justified. Of interest, however, is the fact that of the forty-four specimens subjected to pathologic grading on a basis of 1 to 4, thirty-one (70 per cent) were graded 2.

Although all of the patients subjected to colocolostomy did not have carcinomas of the sigmoid, nevertheless the lesions of members of the two groups are similar enough to point out a few comparisons, in spite of the fact that each group was small. It will be recalled that the average duration of life for thirty-six patients who survived colocolostomy in the first group

was 11.5 months and that the primary operative mortality was 14 per cent. In contrast, are the statistics derived from the present (second) group, in which there was an average survival of 16.5 months and a primary mortality of 18 per cent. It should be recalled that for some of the patients in the former group, colocolostomy may have been more feasible and expeditious than an exteriorization procedure.

It is freely recognized that the choice of therapeutic procedure for an inoperable carcinoma of the sigmoid is fraught with difficulty. The surgeon must consider the degree of risk involved, the probable expectancy of life for his patient and the degree of palliation expected from any particular operation. Primarily, intestinal obstruction must be relieved or averted. Therefore, three avenues of approach are open to the surgeon: performance of (1) colostomy above the situation of the lesion; (2) colocolostomy or a short-circuiting procedure about the neoplasm if the latter is favorably situated; and (3) exteriorization or extraperitoneal resection. If obstruction of any appreciable degree is present, an intra-abdominal procedure involving suturing of the partially devitalized bowel is hazardous and is contra-indicated. A vent for the fecal stream must be provided. This may be done in many cases almost as easily by exteriorization of the malignant lesion as by the creation of a double-barrel colonic stoma or cecal stoma. In addition, removal of the growth may have some part in increasing the expectancy of life of such patients. It must be emphasized that these considerations are but generalities and that for a particular patient the surgeon must think of the condition of that individual as a special problem. He should also remember that his estimate of risk is subject to error and that every possible advantage should be given these unfortunate people.

Summary and Conclusions

1. Prime observations concerning a group of fifty-five patients, for whom palliative resection of the sigmoid for inoperable carcinoma was performed, have been reviewed.

2. Comparison of these observations with those made concerning a group of individuals subjected to colocolostomy, reveals a slightly lower primary surgical mortality and a shorter duration of life postoperatively for members of the latter group.

STARTING THE PRACTICE OF MEDICINE*

J. M. HAYES, B.S., M.D., M.S., F.A.C.S.
Minneapolis, Minnesota

UNDER this subject we shall discuss the following: choosing a location, problems of the young physician, his relation to his fellow practitioners and hospitals, regulation of fees, choosing between individual and group practice, and his responsibility for the future of the profession.

In this class, we shall assume that we have, in embryo, a representative of every branch of the profession.

To give each of you the proper advice for your future guidance in the various chosen pursuits is beyond anything I would attempt to do. What I am going to say to you today should apply to the average student who graduates from this or any medical school. In order to qualify for such advice, one's own medical experience must necessarily have been considerably varied.

If you will pardon me for a brief personal reference, I will just mention the various experiences I have had since leaving this University Hospital in 1911. First I spent five years practicing in a small town in the western part of this state; then five years at the Mayo Clinic, including one and a half years in the Great War. Since then I have practiced in Minneapolis, during which time I have always been connected in a comparatively small way with teaching in this medical school.

For my own satisfaction, it has given me a chance to come in contact with not only widely different types of practice, but perhaps more

*Delivered to Senior students at University of Minnesota Medical School, May 10, 1940.

widely different types of men. It is always interesting to observe the various attitudes of men, in general practice, in highly specialized group practice, and the full time research and teaching positions, toward the real practice of medicine.

The first question each student asks himself when contemplating the beginning of practice, is: Where shall I locate? This, I think, properly should be the first question. Fortunately not all are suited for the same kind of practice. A small percentage of you will be attracted to laboratory work, research or teaching positions. It has been estimated that about 10 per cent of each class take up this sort of medical work. All of you will want further school work. If you have the inclination and are financially situated to do so, I advise you to go on now. If your course is interrupted, you may never get back to study and reach your goal. If this is likely to happen, I believe you should continue your school work now. However, I would like to see every physician, no matter what his future career, put in some time in the general practice of medicine.

As stated before, as we come in contact with the men in various fields of medical work, it is interesting to note the various attitudes of these men. They seem to vary according to the type of work chosen.

To care for the sick is the ultimate aim of every man who enters the medical profession. Even a short time in the general practice of medicine fosters understanding and a coöperation at a later date on the part of the specialist.

Many of you will be anxious to get started in the real practice of medicine. Self-preservation is the first law of life. After this long financial drain, you will feel that you must get out where you can begin to get some financial return on your investment.

After living here for some time in the glare of the city lights, many of you will hesitate to take up a rural practice. The recent depression, poor crops, low prices, and other numerous obstacles have made rural practice appear less attractive. Neither is it so convenient to attend medical meetings, call in consultation, and make free use of laboratory aids. In spite of all these obstacles, many of you will practice in rural districts and be successful.

Some of you with little or no experience in living in the country may have difficulty adjusting yourselves to the situation, for, in order to be successful, you must became a part of the community in which you locate. Many of you will be able to adjust yourselves to any situation you happen to face.

At present there is much agitation about the dearth of rural physicians. This need is much exaggerated. Our survey of this state does not show any great shortage of rural physicians. There are some isolated, sparsely populated areas in the northern part of the state in which physicians are widely separated. The few people who reside in these areas must expect to travel some distance for medical care. Even with government subsidy it would not be feasible to establish first class medical care close to these people. Our investigation has shown that it is not so much lack of medical care in these districts as it is indifference or lack of education on the part of certain groups. Physicians within reach have never refused to go many miles to see these patients or give them adequate care, even with no prospects of financial return. The State Medical Association not long ago requested through the newspapers throughout the state information regarding those who had been unable to obtain adequate medical care. About 200 replies were received. These replies showed definitely that these people could not be satisfied or that they did not know how to avail themselves of the medical care provided for them.

Granted that there is no scarcity of medical men in this state, the normal retirement and loss by mortality will make room for those of you who wish to take up general practice in the rural districts.

Nothing will cause you more apprehension when you contemplate starting out to practice than that you may have to sit in an empty office waiting for patients. To avoid this, many start out on small salaries. This is all right provided you are building for the future. If you have opportunity thereby to come in contact with good material and to obtain valuable experience, you will have made a wise choice. You will at least keep busy and have a chance to show what you can do. If you do your work well, not only the physician with whom you work but also the patients will soon recognize your ability. Soon you will establish yourself as a practitioner of medicine. Whatever presents itself from then on, you should be ready to cope with.

If you accept a small salary from some county,

state or federal agency, in which there is little chance for advancement, then I think you will make a mistake. Occasionally a physician accepts a small salary from some of these agencies to take care of a practice which justly belongs to the local physician. County Boards have done this in the past. Today the Minnesota state law gives the indigent patient the right to choose his own physician.

In he large cities the indigent patient is still taken care of largely without remuneration to the physician, but in the rural districts this is not the case. An agreement with the various boards responsible for the indigent, allows the physician a fixed, reduced fee for the care of these patients in rural areas.

While there will be disadvantages, mentioned before, in the ordinary rural practice, you will have many advantages that the city practitioner never experiences. Here you are thrown on your own responsibility. You must make decisions by yourself. You must develop initiative. You will have to make your diagnosis frequently without having laboratory men or consultants to make them for you. This work will frequently develop your judgment to a surprising degree. I have in mind a man with whom I came in contact when I first started to practice in the country. Although he was a comparatively young man, he had practiced several years. When he received his medical education not even a high school education was required for entrance to the medical school. Then there were medical schools giving courses of two or three years. A medical degree was not required to practice medicine. If one could get by the State Board examinations, he could practice medicine. This man had such a limited scientific education. But he really had learned the "art" of the practice of medicine. He was untiring in his efforts to please the patient. He had acquired all the qualities necessary to attract and hold his patients. He was always neat, clean, sympathetic, mildly humorous, and tolerant to the highest degree. He did everything possible to give the patient relief, even if it was only temporary. Then he got down his books and worked and studied that he might give the patient the best he could.

While he started out a very young man with a very limited scientific education, he eventually became one of the highest types of the old time family physician. Rarely did his patients go elsewhere without consulting him. After fifteen or more years in country practice, he took up special work and now is a successful specialist.

The recent rapid development of county medical societies and the continuation courses here at the University of Minnesota give the rural physician a good opportunity to keep up with the rapid development of medical science. No state gives the rural physician better opportunities to keep abreast of medical progress.

Some of you will become rural physicians. These small communities will need you. Some of you will be contented to remain there, and will become not only successful physicians but the most influential citizens in the community. Some of you may desire to get away later. Even if you do, I am sure you will consider such practice a valuable experience in your life. Many of our most successful specialists in the city now, began as rural physicians.

If you begin general practice in the city, after your year of hospital internship, you will encounter many of the same obstacles that your contemporaries will in the rural districts. Competition will be more keen. More often your patients will go to another physician without even hinting to you that they are going. You must learn to expect this and not take too great offense from it. Perhaps the patient has shown good judgment. You must cheer up. Try to forget the loss of this patient and learn by the loss of this one how to hold the next. If you feel that the patient is not satisfied or that you are not succeeding with the patient, it is often wise for you to be the first to suggest consultation.

Our profession must uphold the right of free choice of physician for every patient. If a patient is examined by you and is not satisfied with your opinion, he has the right to consult any other physician he may desire.

Again, in starting general practice in the city, it is usually advisable to work with an older man who has a well-established practice, if that is feasible. First, be sure that the older man holds the respect of the profession and the community. You may be tempted to practice with a man who has a very large practice but who has obtained this practice by unfair or unethical means. He may not retain this practice for long if his principles are unsound. A man with little experience may have difficulty in judging an older man's standing.

You have learned quite well the scientific side of the practice of medicine. With the older established man you will not only add to your knowledge of scientific medicine but you will learn something of the art of the practice of medicine. A noted medical man has said that the latter is of about equal importance with the former so far as your success in the practice of medicine is concerned.

Many fanciful and bizarre plans for the practice of medicine are being put before the young man of today. Beware. Do not enter into any unusual plan until you have studied it carefully. A plan that may be attractive to you today may serve to mar your future. Your county and state medical society, as well as some of your older confreres, stand ready to advise you in all these matters.

Peace and harmony is important in all walks of life. Perhaps in no walk of life is it more important than in the practice of medicine. Always strive to coöperate with your medical confreres. You may think, as some already have, that you are going to establish prestige by criticising your competitors. Do not do it. Some day you may need their assistance. Whatever mistakes they have made, you may make sooner or later. The longer one practices, the more he realizes the value of the friendship of his fellow physician. A noted physician once said: "Never throw mud at the other fellow. If he throws mud at you, strive to get so far ahead of him that he cannot reach you." Jealousy or the lack of skill on the part of the offender, is frequently evident in these cases.

Sir William Jenner said: "Never believe what a patient tells you the other doctor said." Remember, patients will misinterpret what you say as well as what the other doctor said. Complaints coming to our medical societies bear out the truth of the above quotation. Many malpractice suits have their beginning in unfortunate remarks of a physician made relative to the work of his competitor. It behooves us all to be especially cautious in our comments on the work of the other fellow.

No physician can carry on a large successful practice without being intimately associated with a well-standardized hospital. If you practice in a rural area, you may have to conduct your own hospital or be closely allied with the management thereof. I would like to see every practicing physician put in a position where he would have to become acquainted with the trials and tribulations of hospital management. The average physician little realizes how often unfair patients and lawyers take advantage of unavoidable accidents in the hospital. An accident may be entirely the fault of the patient, yet frequently exorbitant damages are recovered from the hospital. Unfortunately, a careless remark by a physician may be the spark that starts the conflagration. Every first class hospital should have the undivided support of the attending medical staff.

The same Code of Ethics applies wherever you locate. Read this Code carefully. Some day you will be pleased that you have subscribed to this Code. There is no greater satisfaction in the world than to have followed a noble profession, lived up to all the rules and regulations, and held the respect of your profession and community. The value of such a career cannot be measured in silver or gold.

You here today have been sifted out of many more who started out with you several years ago. You are the sole survivors in the process of elimination. Wherever you go or whatever you do, be determined to be successful. Your success will not be measured merely by your financial gain, but more by what you have given to your profession and your community. Determination and a will to succeed are in your make-up or you would not have come this far. Having come this far, you must keep before you the rest of your lives the ideals of your profession.

Your teaching in school has dealth largely with the care of the patient with organic disease. In practice, you will be surprised to see so many sick patients in whom you can find no evidence of organic disease, yet must be treated by you.

The therapeutics of functional diseases, psychoneuroses, or, according to Crile, pathologic physiology may be your greatest problem. Because you do not find organic disease does not necessarily mean there is none present. Neglect or improper treatment of these patients by physicians of the past has had much to do with the presence of cults in our midst today. Never tell a patient there is nothing wrong with him or to go home and forget about his ailment. There is something wrong or he would not have come to you. Try to discover his trouble and remedy it if possible. Study these patients carefully. If you are not satisfied that you can help them,

call in consultation. Try to relieve their suffering, even if only temporarily. Then study some more. Do not overlook any detail. Do not give them up to the cults. You will be the defenders of the profession in the future. You cannot legislate the cults out of existence. Their personalities and salesmanship are ready substitutes for appropriate medical care. Your foundation, your training and standing render you the most capable persons for the care of the sick, whether or not their illness has a pathological basis.

The success of the chiropractors and other cults is well inferred by a remark of the late Dr. Charles Mayo. He said, "Rub a dog's back and he's your friend." The cults have won the friendship and confidence of these unfortunate people who need sympathy and friendship, by rendering them just such service. With the help of your confreres, you can and should be able to hold these patients.

While I do not believe we should spend our time and efforts talking about or condemning the cults, I do not agree with the medical man who believes we should sit back and let the cults thrive by exerting undue influence on our legislators or state officials. I am convinced that if the medical men of the past had put forth sufficient effort, few of these cults would have been licensed to practice their pseudo-magic on deluded people. You will be the only properly trained group to see that healers outside your profession do not gain footholds in the future. Do not let politicians or other outside groups control the practice of medicine. Outside control means chaos and inferior medicine.

The State of Minnesota is today notable for the coöperation which exists between the legislators and state officials and the medical profession. Minnesota is one of only thirteen states in this country that has been successful in enacting a Basic Science Law. When you learn that not more than a dozen healers outside your own profession have been able to pass the Basic Science examinations during the past twelve years, you may realize something of the importance of this law.

To preserve these accomplishments in your state requires constant vigilance. The responsibility for maintaining this vigilance will be yours. Do not shirk it. No matter how busy you are, take time to study the economic side of practice and learn the inroads outsiders are trying to make on your profession.

Socialized or government controlled medicine has recently been a subject of much discussion. Study this subject for yourself. You will be surprised to learn how many apparently intelligent people have been deluded sufficiently to make them advocate this system of practicing medicine. You will find on investigation that the agitation for such a sysem is fostered largely by political racketeers, social workers, commercial magazine writers, or medical men who know little about the real practice of medicine. Usually you will find there is some selfish interest at the bottom of any promotion in this direction. It always means the control of the practice of medicine by the politicians.

No greater opportunity for graft could be offered for politicians than the control of our profession. In Germany, under government control, 40 per cent of all money paid in for medical care is used in administration. Some recent bills introduced into Congress, if they become law, would do much to put us under federal control. It is you who must not only care for the sick but also must control that care.

In the matter of fees for your work, you will usually have little trouble. Fees for medical work vary in different communities. After much discussion between medical representatives and lay groups, a fairly uniform fee schedule for the indigent has been established in this state. This you will always obtain from local authorities in rural communities. In Hennepin County a minimum fee schedule has been adopted for the average patient. This was mainly a defense measure. Many compensation insurance companies have exerted influence to cut medical fees to an unreasonable degree. In areas where the overhead expense is less, the fees are naturally less.

Some of you will be asked to join medical groups for the practice of medicine. There are quite a number of successful groups carrying on today. Not many medical men are leaders. It takes real leaders to successfully head medical groups. Medical men are naturally individualists. The extensive training of the medical man fits him for independent thinking. It is usually difficult for him to subjugate his ideas to those of a leader. In a successful group, the ideas of all usually must conform to those of the leader. A chain is only as strong as its weakest link. A

medical group built with every department up to standard, with unity of purpose throughout, should give the greatest efficiency in the practice of medicine. This does exist in some medical groups. If you are fortunate enough to join such a group, you will make no mistake. Such opportunities, however, are rare.

No matter what kind of practice you enter, no matter what branch of medicine you specialize in, your success will be determined by the degree in which you measure up to several determining factors. First among these factors we must place your scientific attainment. You must keep abreast with medical times. You must attend medical meeings, and read good medical literature. Do not fall into the habit of letting the drug houses furnish you your only medical literature.

A notebook in which to keep notes of unusual symptoms and unusual cases, as well as important excerpts from medical literature, is often a valuable aid. From this you may gain knowledge readily when you most need it.

Important as is your scientific knowledge, it only slightly outweighs the importance of your knowledge of the art of the practice of medicine. In this, your ability to know human nature and efforts to please the patient from every point of view are the important elements.

Your appearance, your sympathy for the patient in his suffering, and a tolerant attitude to all his whims, help you to hold the confidence of the patient until you have an opportunity to make a diagnosis of his trouble and determine what you may be able to do for him.

Never forget the wise saying of Epictetus: "Know ye that education and skill are a continuous progression and he that addeth not to that he hath, soon loses his store thereof."

In the time allotted you have received the best training for caring for the sick that is humanly possible. Do not miss an opportunity to add to this store of knowledge. Remember there is always room at the top, but do not miss any steps on the way up.

Be true to yourselves, your patients, and your profession, and some day you will be proud of your profession and your profession will be proud of you.

THE PRESENT SURGICAL MANAGEMENT OF ESOPHAGEAL DIVERTICULA WITH PRESENTATION OF A NEW (?) METHOD*

STANLEY R. MAXEINER, M.D.
Minneapolis, Minnesota

THE surgical management of pulsion diverticula is a distinctly controversial subject. All writers agree that when feasible the sac should be removed, and that it may be removed safely in two stages, but much argument arises as to the safety or danger of the one-stage operation. The writer believes that he has a technical procedure not found described in a review of the medical literature which possesses all the advantages of the two-stage operation but which may be entirely accomplished in one stage.

The history, etiology and origin of pulsion diverticula were presented by Cottam,[4] a member of this society. Pharyngeal or pulsion is probably more correct than esophageal diverticula but the latter is still a freely used term, and because of popular usage is so classified by the *Year Book of Surgery*.

The force applied by the constrictor muscles of the pharynx causes a herniation of mucosa and submucosa through a constant area of weakness of the posterior pharynx in the presence of stricture, or a synchronous spasm of the muscles at the entrance to the esophagus. Fibers of muscle follow the herniated sac to a greater or lesser degree and can be adequately separated and used to reinforce the defect after removal of the herniated sac. This has been demonstrated by Kirschner[8] annd used effectively by us. An ingenious contrivance has been devised by Jackson to demonstrate the mechanics of the herniation. The weakened area posteriorly has been described by Killian,[7] Lord Moynihan and others.

Anatomically the fascial planes of the neck continue downward into the chest in such a manner that the interfascial spaces are continuous with those of the mediastinum. Spreading infec-

*Presented at the annual meeting of the Western Surgical Association, Los Angeles, California, December 16, 1939.

tions involving these spaces of the neck rapidly produce a mediastinitis which is usually severe if not fatal. Rea,[11] working with Wangensteen in the study of the gases of obstruction, found that mediastinitis followed one-stage esophagostomy and transverse sections of the esophagus in dogs. Hofer[6] reports one case of mediastinitis with death in fourteen operations for diverticula. Certainly many unreported similar experiences must be the basis for its wholesome regard in esophageal surgery.

Babcock,[1] in his *Surgery,* states, "To prevent mediastinal infection the operation should be done in two stages." However, in 1937 he (Babcock)[2] states that they have performed sixty-five one-stage operations and that he has seen no mediastinitis. Shallow[12] likewise advocated the one-stage procedure, while Harrington[5] advocated the one-stage operation in selected cases, namely small diverticula with a fairly definite neck. His figures, however, showed four two-stage operations to each one-stage operation.

Lahey[10] insists on adhering to the two-stage operation because of its security, based on low mortality, freedom from cellulitis of the neck, mediastinitis and the absence of complications.

The principles of surgical management have been based upon, first, removal of the sac, second, avoidance of infection with concomitant mediastinitis and, third, prevention of recurrence.

The method advocated by Goldman,[9] in which the neck of the sac is ligated with silk thread, the lower end of the incision packed with gauze and the silk thread and diverticulum allowed to slough off, incorporates the principles of the operation which we describe. The sac is not opened, the surfaces of the incision are not contaminated and, therefore, the element of infection is eliminated. Koenig recommends dissection of the sac and its attachment in an upward direction so that it drains rather than fills during the act of swallowing. In this instance, the sac is not removed and as a result, again contamination is eliminated.

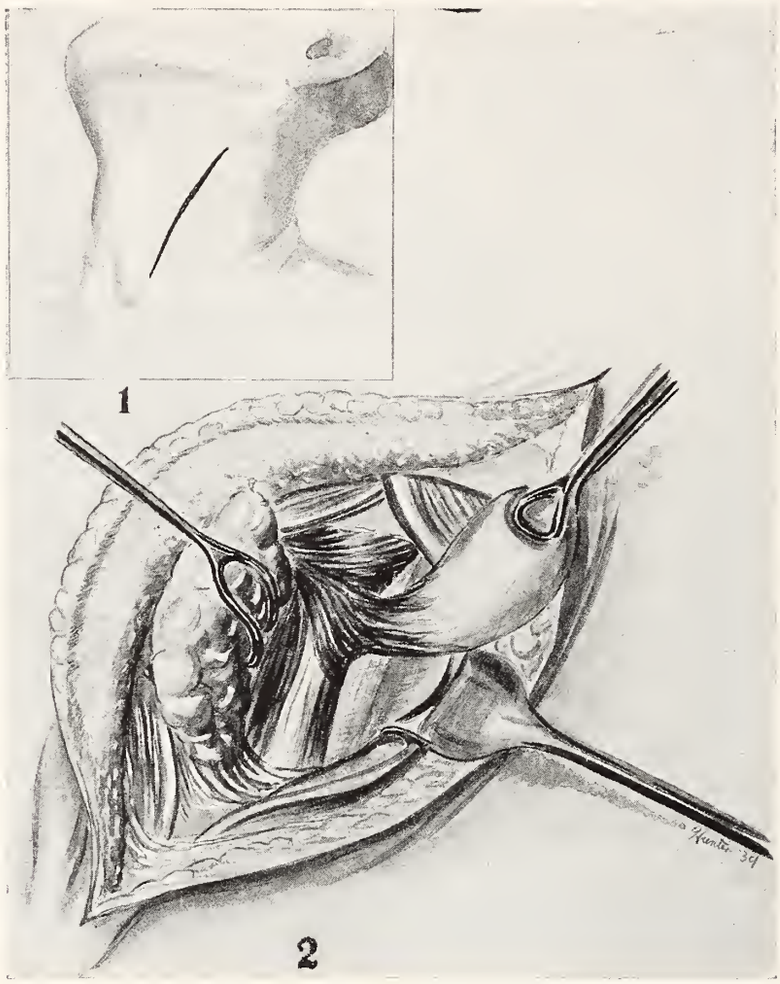

Fig. 1. Incision at the anterior border of the sternochleidomastoid muscle to approach the diverticulum.

Fig. 2. Thyroid retracted medially, great vessels laterally; esophagus and diverticulum freed.

Inversion of the sac into the esophagus has been recommended either through the use of purse strings or by intra-esophageal and extra-esophageal manipulation. With a small neck and some edema of the sac, inversion may be impossible. In one instance reported in which the inverted diverticulum became edematous and by its enormous increase in size threatened death to the patient, emergency removal of the swollen and partially gangrenous sac through the esophagoscope was necessary.

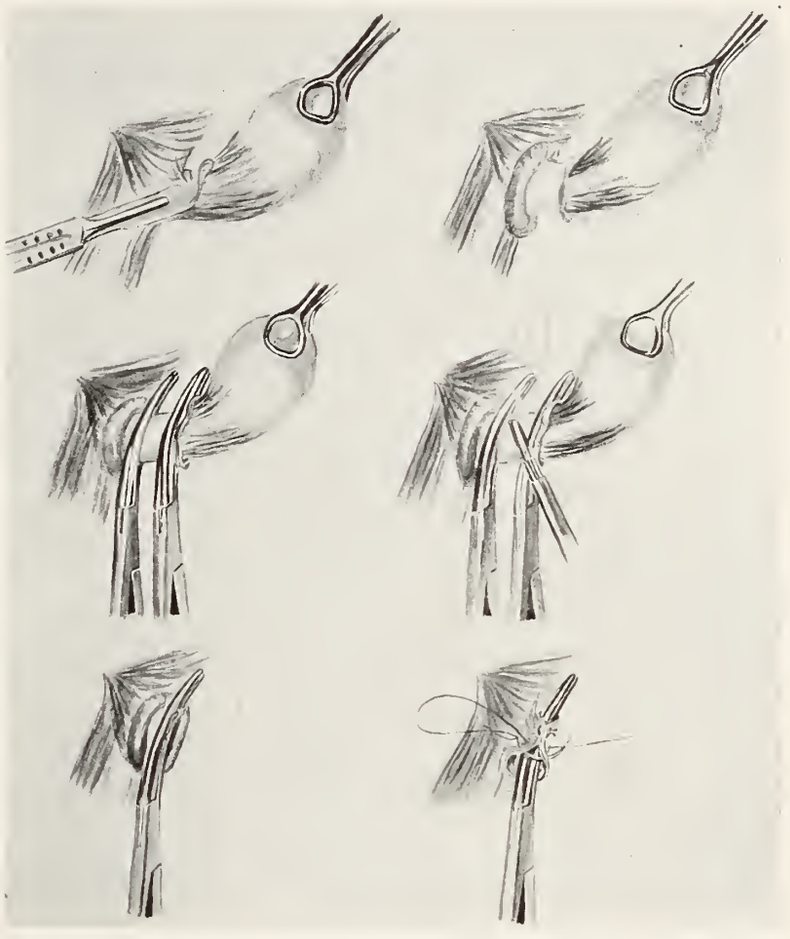

Fig. 3. Six illustrations in which the muscle and fascia surrounding the neck of the diverticulum are divided and separated back to form a cuff. The mucosa and submucosa are doubly clamped and the pedicle divided close to the proximal forceps by actual cautery. The muscle and fascia are sutured over the forceps, which is allowed to remain *in situ*.

The present-day trend of surgical management consists of removal of the sac in one or two stages. Babcock[3] and those associated with Jackson have advocated the one-stage resection, the sac being identified and its dissection facilitated by the use of the esophagoscope. The light may be introduced into the diverticulum if the opening is adequate and the limits of the sac visualized by its red glow. By very careful technic the sac is removed, the mucosa and submucosa carefully inverted and the rent reinforced by approximation of the muscle fibers. The patency of the esophagus is assured by suture of its wall over the esophagoscope. The chief objection to this procedure is that the neck of the diverticulum must be opened. Therefore, the wound is compounded and repeated instances of cellulitis of the neck are reported.

The two-stage operation advocated by C. H. Mayo, Lahey and subscribed to by numerous others has the distinct advantage that the sac is liberated and anchored in an upward direction in the neck but not removed. The wound, therefore, is not contaminated. The lower portion of the incision is packed with gauze which is allowed to remain until the mediastinum is entirely separated by adhesions and granulations. After an interval of ten or twelve days the sac may now be removed with safety because contamination of the wound is not followed by a spreading cellulitis. The two-stage procedure possesses two distinct advantages: (1) the elimination of infection, and, (2) improvement in

the patient's nutrition when the large overfilled diverticulum which has caused interference with the patient's swallowing is transplanted to an upward position. Such technicalities as careful preservation of the recurrent laryngeal nerves which lie in the tracheo-esophageal angle and prevention of narrowing of the esophagus should always be observed. Lahey has warned against undue division and ligation of large thyroid vessels, as occasional instances of fatal secondary hemorrhages have occurred.

We have chosen to present for your consideration a technical procedure which we believe possesses all of the merits of the two-stage operation, most important of which is elimination of wound contamination and infection but which may be accomplished by a single operation.

Case Report

A white man, aged forty-eight, came for treatment with the complaint that he has had increasing inability to swallow for about two years. He stated that he had had a gurgling in his throat which came on after eating. The condition had been growing progressively worse. At present besides the difficulty in swallowing he had to spit up a considerable quantity of food after eating. His impression was that solid foods passed more readily into the stomach than did liquids. There was no pain before, during, or after eating. His family history, personal history and past illnesses are essentially unimportant.

Examination revealed a well developed, well nourished male with a completely normal physical examination. X-ray examinaton with an opaque medium showed a pouch which filled completely and which measured 7.4 centimeters vertically by 4 centimeters laterally. After the pouch was completely filled the remaining portion of the food entered the esophagus normally.

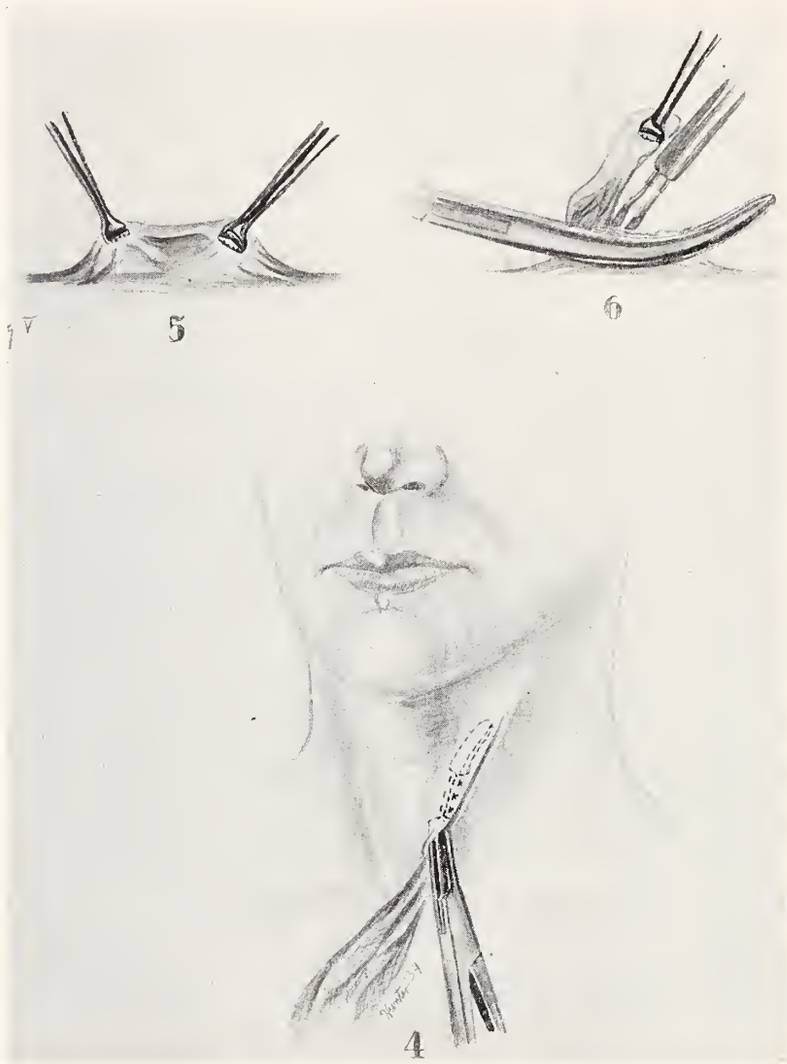

Fig. 4. A small gauze pack over the mediastinum escapes over the lower angle of the incision together with the forceps, which has been left across the stump of the diverticulum. The wound is closed throughout the rest of the incision.

Fig. 5. The lateral wall of the esophagus of a dog is lifted by two Allis forceps to make a tent.

Fig. 6. The overhanging tent-like portion of the esophagus is cut away by actual cautery, which was examined to be certain that it contained mucosa and thus be assured that we had opened into the esophagus. The forceps is allowed to slough off.

Diagnosis.—Diverticulum of the esophagus.

Technic of operation.—A standard incision was made along the sternomastoid muscle, the thyroid was retracted medially and the great vesels laterally. The sac was identified and found to lie behind and to the left of the esophagus, extending downward into the superior mediastinum. It was dissected free to the attachment of its neck into the pharynx. The entrance to the mediastinum was carefully walled off with gauze and the muscle and fascial fibers which covered the proximal portion of the neck were separated by sharp and blunt dissection so that there was a definite cuff surrounding the stump. Two pairs of curved forceps were then applied to the neck and the sac divided close to the proximal forceps by actual cautery. This efficiently removed the sac, together with the distal forceps without any contamination.

It occurred to us that we have never hesitated to leave a forceps on the vessels in a difficult vaginal hysterectomy or in nephrectomies where ligation of a short pedicle or the condition of the patient seemed to indicate. As a result, the cuff, which had been carefully pushed back and preserved, was sutured over the forceps. The gauze packing was removed and the forceps only escaped through the lower angle of the incision. The forceps fell off on the sixth day and there was a persistent serous drainage for approximately one week. The wound healed completely by the end of three weeks and the patient made a normal, uneventful convalescence.

We have had only one opportunity to employ this procedure and we attempted to substantiate our experience by similar operations on laboratory animals in the Department of Experimental Surgery at the University of Minnesota.

The side of the wall of the esophagus of a dog was exposed and elevated like a tent by two Allis traction forceps. A curved forceps was then applied, the base and the points protruding beyond the esophageal wall similar to the technic recommended for the Kerr-Parker aseptic intestinal anastomosis. The protruding segment was removed by electrocautery and the removed portion carefully examined to be sure that it contained mucosa and thus determine definitely that the lumen of the esophagus had been entered. A gauze pack was placed over the superior mediastinum and the forceps allowed to escape with the gauze at the inferior angle of the incision. The forceps separated and fell off by itself at the end of five days. There was a small amount of watery drainage from the neck which persisted over a period of three days. The gauze was removed and healing was complete in eight days.

This procedure has subsequently been performed on three additional animals. In each one, the forceps separated spontaneously at the end of four to five days. There has been a watery fistula present for a period of three to eight days, but in no instance was there any cellulitis of the neck or mediastinitis. One of the animals has subsequently been sacrificed for other purposes and autopsy examination showed healing of the esophagus to be so complete that it was virtually impossible to determine the point from which the scallop of esophageal wall was removed.

The following graph shows the results obtained in four laboratory animals:

	Clamp Off, Days Postoperative	Fistula Dry, Days After Clamp Fell Off

Conclusions

Pulsion diverticula occur in people usually past middle life and may occur in individuals with concomitant heart disease, malnutrition, et cetera. As a result, we feel that a safe one-stage operation would have a decided advantage. We believe that the one-stage technic which we have presented possesses all of the elements of safety, particularly the elimination of mediastinitis.

Note—Subsequent to the presentation of this paper, Dr. Carl Rice and Dr. Clarence Arlander performed an operation by the same technic for diverticulum at St. Barnabas Hospital. The patient was extremely emaciated. The forceps fell off on the sixth day, the wound healed promptly and the patient made an uneventful recovery. She gained weight rapidly and has returned to normal health.

Dr. Owen Wangensteen, Chief of Surgery at the University Hospital, performed an operation at the University Hospital for diverticulum, likewise using the same technic as described in this paper. In this instance the forceps again fell off spontaneously, the wound healed in a few days and the patient made an uneventful recovery.

The series is now made up of three cases successfully operated by this method.

POSTMORTEM FINDINGS IN CASES OF DIABETES*

THOMAS J. DRY, M.B. and CARL F. TESSMER, M.D.
Rochester, Minnesota

THE introduction of insulin not only has markedly reduced the number of deaths caused by diabetic coma, but it has made possible a dietary regimen which closely approximates normal physiologic requirements. Two results of such a revolutionary change in management may be expected. On the one hand, diabetic patients are allowed to live longer than they did before the discovery of insulin; therefore, more of them have degenerative complications of old age and other diseases common to the later decades of life. On the other hand, better nutrition and better control of their metabolic condition conceivably may oppose the development of complications to which such patients formerly were predisposed. While the literature already contains a valuable store of information concerning the pathologic changes associated with diabetes, the trends under new conditions can only be ascertained by the periodic appraisal of new material.

Material

The present study supplements the report of Wilder, which was based on the postmortem findings in eighty-one cases of diabetes. Most of these cases were observed in the pre-insulin era. Our report is based on: (1) a clinicopathologic study of 182 cases of diabetes which were observed in a period of about eleven years (October 1, 1925, to December 31, 1936, inclusive), (2) a microscopic study of the pancreas in 201 cases of diabetes, most of which are included in the 182 cases which have just been mentioned, and (3) a microscopic study of the pancreas in fifty consecutive cases in which patients who came to necropsy did not have diabetes. Necropsy was performed in 139 of 182 cases of diabetes in which clinicopathologic observations were made. Of the 201 cases of diabetes in which the pancreas was examined, twenty-five were observed in the pre-insulin era, that is, prior to 1923, and 176 were observed in the years 1923 to 1937, inclusive. The sections were stained with hematoxylin and eosin. In most cases two sections of the pancreas were available for study, one section of the head of the organ and one section of the tail. In the fifty cases in which the patients did not have diabetes the sections of the pancreas served as controls.

Clinicopathologic Data

In the 182 cases in which clinicopathologic observations were made, 106 of the patients were males and seventy-six were females. The ages of the patients ranged from one to eighty-nine years. In 91 per cent of the cases the patients were more than forty years of age and in 81 per cent of the cases the patients were more than fifty years of age. The average age of the patients at the time of death was 59.5 years, which is almost five years more than that reported by Wilder in 1926. During the period in which the 182 cases were observed, 5,478 new patients who had diabetes registered at The Mayo Clinic.

Events Which Constitute a Serious Threat in Cases of Diabetes

Diabetic Coma.—Table I summarizes the details regarding twenty-two cases in which the diabetes was uncontrolled at the time of death. It will be seen that coma was uncomplicated in only six cases and that in most of the six cases

TABLE I. CASES IN WHICH PATIENTS WERE IN DIABETIC COMA AT THE TIME OF DEATH.

Case	Age, years	Sex	Associated pathologic changes	Comment
1	1	F		Moribund when treatment was started
2	7	M		Failed to respond to treatment
3	8	F		Diabetes resisitant to insulin
4	10	F		Failed to respond to treatment
5	10	F	Atrophy of suprarenal cortex	Failed to respond to treatment
6	28	M		Died elsewhere
7	30	M		Diabetes neglected; patient was a prisoner and was in coma many times
8	39	F	Hyperthyroidism	Died following thydroidectomy
9	43	F	Bronchopneumonia	
10	47	M	Exophthalmic goiter	Diabetes resistant to insulin
11	51	M	Diabetic gangrene	
12	52	F	Septicemia	
13	52	F	Vesicovaginal fistula	Fulminating onset of diabetes following operation
14	52	F	Cellulitis of arm	Refused hospitalization
15	55	F	Pyelonephritis	Moribund when first seen at the clinic
16	57	F	Gangrene	
17	67	M	Coronary occlusion	Diabetes resistant to insulin
18	67	F	Cellulitis of arm	
19	67	F	Coronary occlusion	Diabetes resistant to insulin
20	67	M	Hypertrophy of prostrate gland and uremia	Fulminating onset of diabetes following operation
21	68	M	Hypertrophy of prostrate gland and uremia	
22	71	F	Gangrene of leg; coronary occlusion.	

the patients were seen only after diabetic acidosis had been present for some time.

The incidence of coma in the 182 cases was 12.1 per cent. As should be expected, this was much lower than the incidence of 41 per cent in the series of cases reported by Wilder. As previously stated, most of the patients in Wilder's series of cases were observed in the pre-insulin era. Table I also shows the seriousness of such complications as acute infection and hyperthyroidism.

Overwhelming Infection.—In thirty-four, or 18.7 per cent of the 182 cases, an overwhelming infection was the primary cause of death. This figure does not include postoperative infections such as peritonitis, bronchopneumonia and infections of the blood stream, which are considered under the diseases for which surgical treatment was carried out. It does, however, include three cases in which gas bacillus infection of the stump followed amputation for diabetic gangrene. Erysipelas, bronchopneumonia, cellulitis and septicemia arising from superficial infections contributed mainly to the death of the patients in the thirty-four cases. The majority of the patients in these cases were well past middle age.

Tuberculosis.—For many years we have been struck by the infrequency of tuberculosis among

diabetic patients treated at the clinic. In only one case in this series was a positive diagnosis of active tuberculosis made, and in this case the diagnosis was made fortuitously. The patient had a carcinoma of the stomach that was associated with palpable cervical lymph nodes. One of these lymph nodes was removed for biopsy and was found to be tuberculous. In five additional cases the pathologist was able to demonstrate foci of active tuberculosis in what appeared to be healed pulmonary lesions. Similar lesions were reported in the hilar lymph nodes in four cases. In one case examination disclosed chronic tuberculosis of the pancreatic lymph nodes and in another case a tuberculous lesion was found in the liver. Some form of active tuberculosis, therefore, was encountered in twelve, or 8.6 per cent, of the 139 cases in which necropsy was performed, yet in none of these cases was tuberculosis the principal cause of death.

Degenerative Diseases.—Disease of the coronary vessels. Many authors have commented on the high incidence of degenerative vascular disease among patients who have diabetes. In 130 of the 182 cases the patients were more than forty years of age. The condition of the heart was noted at necropsy in all of these 130 cases. Coronary occlusion was the cause of death in fifteen, or 11.5 per cent, of the 130 cases. In these fifteen cases, nine of the patients were men and six were women. At the time of death the average age of the nine men was sixty years and that of the six women was sixty-five years.

Coronary sclerosis grade 3 or 4 also was present in fifty-three additional cases. In thirty-four of these cases the patients were men and in nineteen of the cases the patients were women. The mere presence of some sclerosis is an expected finding since it occurs among a high percentage of nondiabetic patients who are past the age of forty years. Including the fifteen cases in which death was due to coronary occlusion, coronary sclerosis grade 3 or 4 was present in sixty-eight, or 52.3 per cent, of the 130 cases. In these sixty-eight cases the diagnosis of severe coronary sclerosis was based on one or more of the following criteria: (1) recent or healed infarction of the myocardium, (2) fibrosis of the wall of the left ventricle, which is indicative of coronary insufficiency, (3) a history of angina pectoris, and (4) electrocardiographic findings, such as, for instance, bundle-branch block.

Willius, Smith and Sprague made a study of the incidence of coronary and aortic sclerosis in 5,060 consecutive postmortem examinations. They found coronary sclerosis grade 3 or 4 in 431, or 12.3 per cent, of the 3,513 cases in which the patients were more than forty years of age. Our series does not include a sufficient number of cases to warrant a comparison of the incidence of coronary sclerosis, according to the age of the patients, in the two series of cases, but there seems to be no doubt that the incidence of the severe forms of coronary sclerosis is significantly higher among diabetic patients than it is among patients who do not have diabetes. This has been borne out by the observations of Root, Bland, Gordon and White.

It is only fair, however, to say that in 870, or 17.2 per cent, of the cases reviewed by Willius, Smith and Sprague necropsy did not disclose any evidence of coronary disease. In 367, or 42.2 per cent, of the 870 cases the patients were in the first decade of life and in 795, or 91.4 per cent, of the 870 cases the patients were less than fifty years of age. Normal coronary vessels were not found in any of the cases in which the patients were in the eighth, ninth and tenth decades of life. The incidence of normal coronary vessels decreased as the age of the patients increased.

Diseases of the Peripheral Vessels.—A severe form of peripheral arteriosclerosis was present in fifty-one, or 28 per cent, of the 182 cases in which clinicopathologic observations were made. Gangrene or trophic ulcers occurred in thirty-one cases, and in twenty cases there was sclerosis of the vessels of the legs, which was of sufficient degree to cause clinical evidence of circulatory insufficiency. An analysis of the findings in the fifty-one cases furnished enlightening information. Since the changes in the two groups of cases differed only in degree, the cases will be considered as a single group.

Severe disease of the coronary arteries also was present in forty, or 78.4 per cent, of the fifty-one cases. Acute coronary occlusion was the primary cause of death in no less than fourteen, or 27.4 per cent, of the fifty-one cases.

In eighteen cases the patients died as a result of the gangrene. Details regarding the ocular fundi were available in thirty-six cases. In seven-

Total	51		219		32		193		19		26	

teen, or 47.2 per cent, of the thirty-six cases examination of the ocular fundi disclosed either a central, punctate, diabetic retinitis or a mixed vascular and diabetic retinitis. Definite neurologic signs of peripheral neuritis were noted in nine of the fifty-one cases. The association of vascular disease, retinitis (especially a central punctate diabetic retinitis) and peripheral neuritis has been commented on by one of us (Dry[12]) in collaboration with Wagener and Wilder.

Whether or not there is an etiologic relationship between obesity and advanced arteriosclerosis is a difficult question to settle. The maximal weight was recorded in forty-two of the fifty-one cases. In twenty-six cases the patients had weighed more than 200 pounds (90.7 kg.) at some time.

It would seem that medium-sized muscular arteries, such as the coronary and tibial arteries, are particularly prone to undergo marked degenerative changes in cases of diabetes.[4] What we regard as of particular significance is the high incidence of severe arteriosclerosis among women who have diabetes. Table II shows the incidence of severe peripheral arteriosclerosis according to age and sex in fifty-one cases in which the patients had diabetes and in 219 cases in which the patients did not have diabetes. The 219 cases were included in the report of Hines.

This study and others reported in the literature suggest that something inherent in diabetes renders women particularly susceptible to degenerative changes in the vascular system. Such changes are especially likely to occur in cases in which the diabetes has been present for a long time. It is possible that an inherent defect or abiotrophy may exist in the vascular system and in the insulin-producing tissues and that when both structures are involved the physiologic process of aging may assume pathologic proportions.

Diseases of the Cerebral Vessels.—In nine of the 182 cases in which clinicopathologic observations were made death was due to a cerebral vascular accident, but permission to examine the brain was not obtained in a sufficient number of cases to provide information about the incidence of cerebral arteriosclerosis.

Associated Diseases That May Require Surgical Intervention

Cholecystic Disease.—In fifty, or 27.4 per cent, of the 182 cases gallstones were present or the patients had undergone an operation for cholelithiasis. In two of the fifty cases the patients also had acute cholecystitis. In another case, which is not included in the group of fifty, the patient had acute cholecystitis but did not have gallstones. The fifty-one cases in which there was a history or evidence of cholecystic disease may be divided into three groups. Group 1 includes fifteen cases in which the patients died following operation on the gall bladder or bile ducts.

Severe coronary disease was found at necropsy in three of these cases but it was not responsible for the death of the patients. Group 2 includes thirty-five cases in which gallstones were an incidental finding. In seven of these cases the patients died of acute coronary occlusion. In sixteen other cases the patients had severe coronary disease. The coronary arteries were relatively normal in the remaining twelve cases in this group. In the sixteen cases in which there was evidence of severe coronary disease, two of the patients died of a cerebral vascular accident and four patients died of gangrene of an extremity. Group 3 includes one case in which acute cholecystitis was associated with marked coronary sclerosis. Severe coronary sclerosis, therefore, occurred in twenty-seven of the fifty-one cases in which the patients had gallstones or acute cholecystitis. One would not for a moment claim a direct relationship between chronic cholecystic disease and arterial change even though both are in some way related to lipoid metabolism. The data show clearly, however, that in cases in which diabetes is associated with disease of the gall bladder the incidence of vascular disease also is high.

Malignant Disease.—Carcinoma was present in thirty-eight, or 20.9 per cent, of the 182 cases. The site of the carcinoma was as follows: pancreas in six, stomach in six, rectum or colon in ten, breast in six, genito-urinary tract in three, respiratory tract in three and in the liver and gall bladder in four cases, respectively. This incidence is much higher than that reported by other writers who have studied the postmortem findings in cases of diabetes. This may be attributable to the fact that a large percentage of patients who come to the clinic require surgical treatment, or it may be due to the fact that diabetic patients now live longer than they did formerly. In the eighty-one cases which formed the basis of Wilder's report, the incidence of carcinoma was so small that he failed to comment on it. A subsequent survey of his material disclosed one case of carcinoma of the pancreas.

Of particular interest is the relatively high incidence of carcinoma in recent reports of postmortem studies in cases of diabetes. As previously stated, carcinoma was found in thirty-eight of the 182 cases in which clinicopathologic observations were made. In six, or 15.8 per cent, of the thirty-eight cases the carcinoma involved the pancreas. According to McKittrick and Root carcinoma of the pancreas comprises only 4 per cent of all malignant tumors. Warren[13] reported that malignant lesions were found in forty-seven of 527 cases of diabetes in which necropsy was performed. In ten, or 21.2 per cent, of the forty-seven cases the malignant lesion originated in the pancreas. In four of the ten cases the development of the carcinoma antedated the development of the diabetes.

Pathologic Changes in Endocrine Glands Other Than the Pancreas

Thyroid Gland.—In twenty-seven, or 14.8 per cent, of the 182 cases in which a clinicopathologic study was made there was evidence of disease of the thyroid gland. Adenomatous goiter was present in twenty-four cases. In six of the twenty-four cases the adenomatous goiter was associated with hyperthyroidism and in two cases it was associated with acromegaly. A diagnosis of exophthalmic goiter was made in three cases. Thyroidectomy was performed in two of these cases. The postmortem report did not contain any special comment regarding the condition of the pancreas in these cases. Warren[15] did not find any especially characteristic lesion of the pancreas in cases of diabetes in which hyperthyroidism had been present for a long time.

Suprarenal Glands.—In one of our cases the patient, who was thirty-three years of age, died of classical Addison's disease. Necropsy disclosed marked atrophy of the suprarenal glands. In three other cases necropsy disclosed considerable atrophy of the suprarenal cortex. In the first of these cases the patient was a man, aged sixty-seven years, who died of coronary occlusion. Diabetic acidosis could not be controlled despite the administration of large doses of insulin. In the second case the patient was a man, aged twenty-nine years, who died after cholecystectomy. At the time of his death he apparently was in a state of shock; the value for the systolic blood pressure was 96 mm. of mercury and that for the diastolic pressure was 54 mm. In the third case the patient was a boy, aged ten years, who died in diabetic coma. Hyperplasia of the suprarenal cortex was noted in another case. The patient was a woman, aged seventy-one years,

who died of coronary occlusion and diabetic gangrene. In this case the acidosis could not be controlled.

portal vein. He had severe diabetes which had been discovered two years before his death. In both of these cases necropsy disclosed advanced

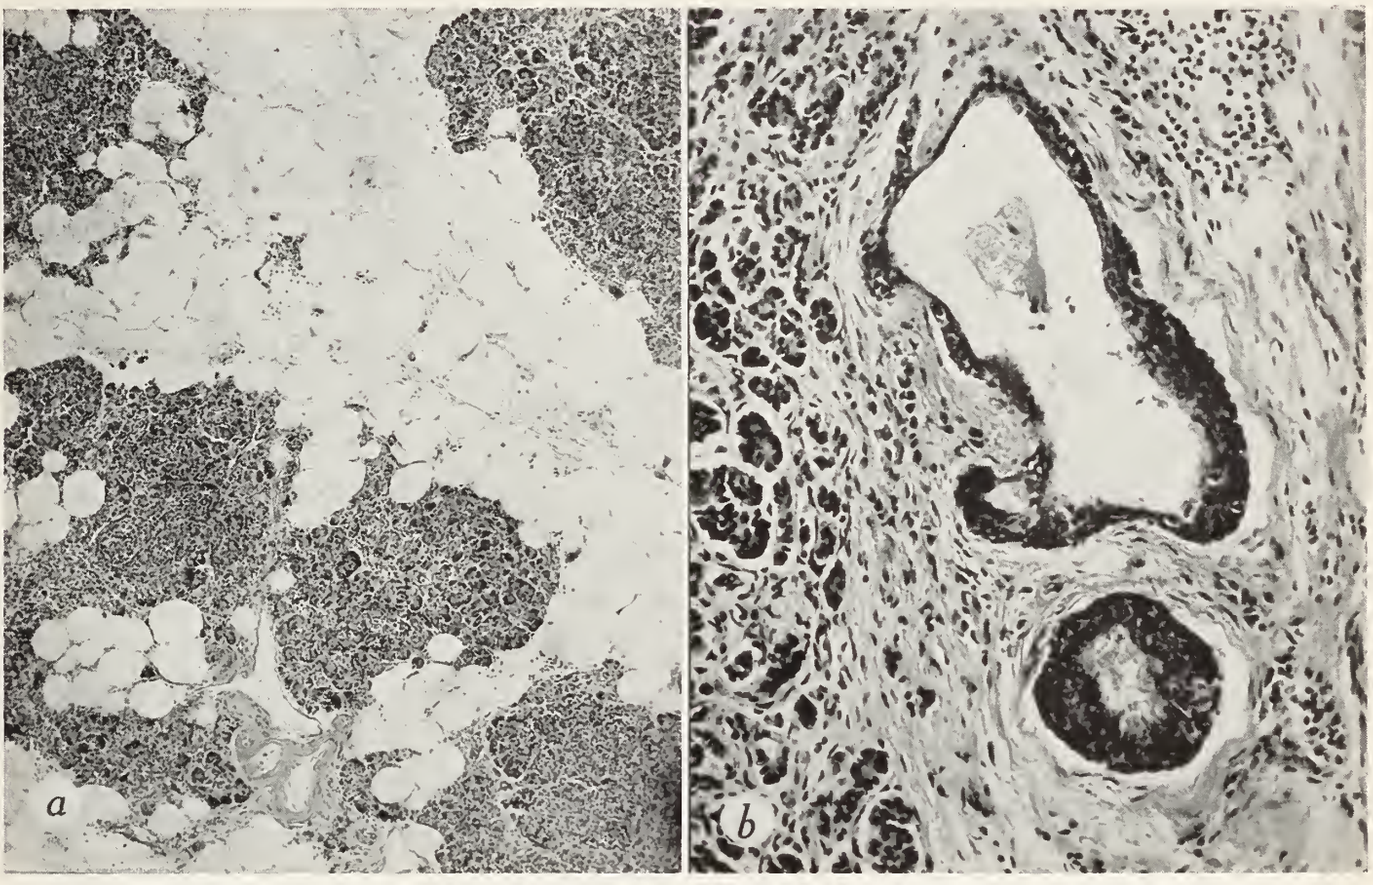

Fig. 1. *a*, Fatty infiltration of pancreas (x55); *b*, duct metaplasia; transition from columnar to stratified epithelium (x170).

Pituitary Body.—In considering the changes in the thyroid gland we said that acromegaly and adenomatous goiter were associated in two cases, in one of which there was clinical evidence of hyperthyroidism. Unfortunately, the number of cases in which the intracranial contents could be examined was small. No anatomic change of the pituitary body was observed. The brilliant studies of Houssay's and Young's experimental production of diabetes in dogs by the injection of extract of the anterior lobe of the pituitary body have prompted a careful study of this organ in cases of diabetes in which necropsy is performed, but thus far no changes of significance have been reported.[3,5,10]

Pathologic Changes in the Pancreas

Pancreatic Calculi.—Pancreatic lithiasis was encountered in two cases. In the first of these cases the patient was a man, aged fifty-four years, who had had severe diabetes for two years. In the other case, the patient was a man, aged forty-one years, who died of thrombosis of the

destruction and fibrosis of the pancreas. These changes no doubt were the result of obstruction and infection of the pancreatic ducts and secondary parenchymatous changes. In cases of pancreatic lithiasis it is probable, as Warren[13] and others have suggested, that despite damage to the acinar tissue the islands of Langerhans may be preserved for some time much in the same manner as they are in the pancreas of an animal after the pancreatic duct has been ligated.

Fatty Infiltration.—This lesion appears as large circular spaces near the vessels and scattered throughout the parenchyma (Fig 1*a*). It is obvious that extremely fatty regions would be avoided in preparing blocks of tissue for sectioning, but the lesion, when present, is probably an indication of acinar atrophy.

Pancreatitis.—This lesion is of two types: (1) interacinar, or diffuse, and (2) interlobular.

Metaplasia of the Pancreatic Ducts.—So-called metaplasia of the pancreatic ducts (Fig. 1*b*) was

noted in ten, or 5.7 per cent of the 176 cases. This incidence corresponds rather closely to that noted by Baló and Ballon. Warren[14] found this condition in nine of 484 cases. In our series of cases there was no evidence that the squamatization had caused occlusion of the pancreatic duct, but the sections were by no means sufficient to permit us to arrive at any definite conclusion.

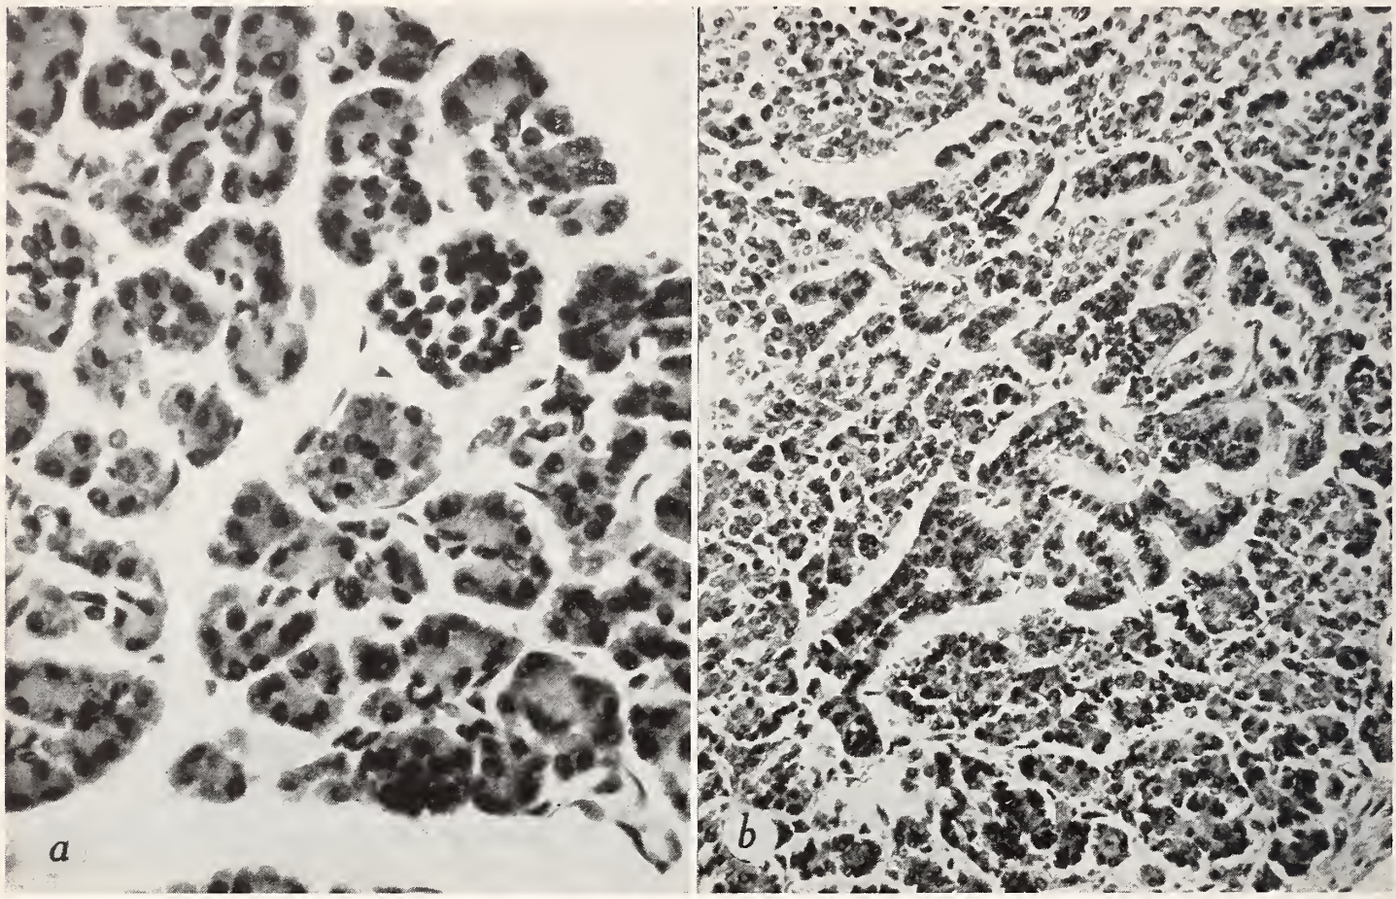

Fig. 2. *a*, Atrophy of islets (x430); *b*, so-called columnar or hypertrophic islets (x185).

Changes in the Islands of Langerhans.—Demonstration of typical changes in the islands of Langerhans in cases of diabetes mellitus has been the aim of many investigators. The object of this aim has been twofold: (1) to confirm the islet theory of the control of carbohydrate metabolism, and (2) to provide a microscopic method of diagnosis of this disease.

The results of extensive microscopic observations by many investigators may be summarized in a general way by stating that certain lesions of the islets are relatively, but not absolutely, diagnostic and that quantitative consideration of function should not be neglected. The latter necessarily implies ability to determine the presence or absence of function by the microscopic appearance of the islets. This determination has often been made without sound basis and it certainly has not been entirely successful.

In this study we made a special effort to observe the changes which had attracted the attention of previous investigators, and an attempt was made to compare these changes in the cases observed in the pre-insulin era and in the post-insulin era. Only certain changes were found to be significant in respect to these two groups of cases. This consideration will be limited chiefly to these changes.

Recent or old atrophy. The islets may be of normal size and be composed of cells with small hyperchromatic nuclei and with or without cytoplasm, or they may be small and compact (Fig. 2*a*) and be composed of small cells which at times are elongated and cells which contain small dense nuclei. In cases in which the cells contain small dense nuclei the postmortem changes offer the greatest hindrance to diagnosis. The presence of a few small dense nuclei, which were indistinguishable from true pyknosis, was encountered in both diabetic and nondiabetic tissue in a number of instances. The assumption that they represented postmortem changes was based

on the similarity to the histologic picture seen when pancreatic tissue was purposely left unfixed for periods which varied to as long as ten hours.

diagnostic significance could be attached to it. Hydropic degeneration is a reversible process[2] within certain limits, and only in cases in which

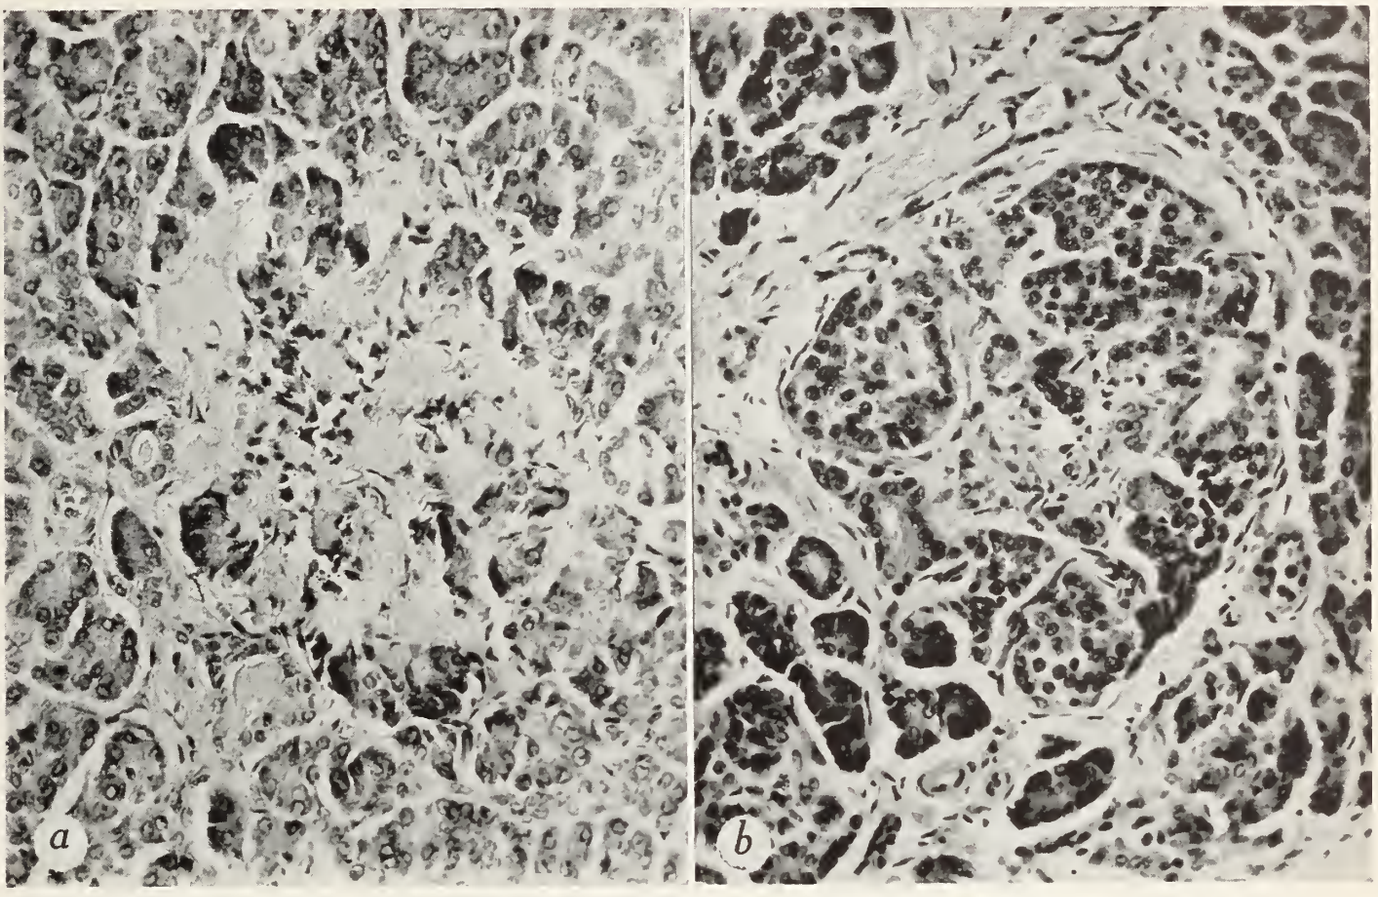

Fig. 3. *a*, Advanced hyalinization (x250); *b*, fibrosis (x235).

Therefore, acute degenerative change was diagnosed only when extensive pyknosis of the islet cells was more or less uniform as regards the stage of development. This was necessary because an average of 7.2 hours had elapsed before the pancreatic tissue was fixed.

Hypertrophy.—The occurrence of so-called columnar or hypertrophic islets (Fig. 2*b*) was noted without reference to degree. It was felt that approximation of the proportionate amount of columnar and simple islet tissue would not be of any significance. The application of some relatively precise method, such as that of Ogilvie, to measure the amount of each type of islet tissue might lead to conclusions regarding the functional value of the columnar portion of the islets. However, what appear to be transitional forms between the columnar and simple islet tissue occur and are difficult to classify.

Hydropic Degeneration.—In our material hydropic degeneration in the stage of vacuolation of the cytoplasm was so effectively imitated as well as concealed by postmortem changes that no diabetes is uncontrolled at the time of death can it be expected at necropsy. Even then it may be simulated by postmortem changes; although these changes may be identified by comparison with the adjacent acinar tissue and by the varying stages of apparent pyknosis, these criteria are by no means conclusive. Our inability to recognize the one lesion considered by many investigators to be of diagnostic significance in cases of diabetes mellitus, namely hydropic degeneration, was an early and definite conclusion.

Hyalinization and Fibrosis.—These changes are easily recognized. They require no comment other than to state that they are at times difficult to differentiate and to grade (Figs. 3*a* and *b* and 4*a*).

Lymphocytic Infiltration.—In our experience this change has been difficult to identify. While there frequently was definite evidence of lymphocytic infiltration in and about the islands of Langerhans (Fig. 4*b*), in many cases, particularly those in which the patients were young persons, there was a reasonable doubt concerning

its presence. Warren[16] expressed the opinion that this was the most characteristic lesion of the islands of Langerhans in cases of diabetes in which the patients were children.

study of the pancreas in 201 cases of diabetes, most of which are included in the 182 cases, and (3) a microscopic study of the pancreas in fifty consecutive cases in which patients did not have

Comment

One of the most interesting results of this study was the information gained by a comparison of the pathologic changes noted in the cases observed in the pre-insulin era and in the post-insulin era. The pathologic findings in these cases were checked with the findings in a control group of cases in which the patients did not have diabetes (Table III). In the cases of diabetes observed in the postinsulin era, the markedly increased incidence of atrophy, hyaline changes, and fatty infiltration, particularly in view of the lack of change in the incidence of pancreatitis, fibrosis and hypertrophic changes, may well be taken as an indication of increased degenerative changes and the results of longer life made possible by the administration of insulin.

Summary

This report is based on: (1) a clinicopathologic study of 182 cases of diabetes which were observed in the postinsulin era, (2) a microscopic

diabetes. In twenty-two cases the patients were in coma at the time of death; uncomplicated diabetes was present in only six of these cases. In the sixteen remaining cases hyperthyroidism or infection was present. Overwhelming infection, such as erysipelas, bronchopneumonia, cellulitis and septicemia, was the primary cause of death in thirty-four of the 182 cases. The incidence of advanced degrees of arteriosclerosis, especially of the medium-sized muscular arteries, in cases in which the patients were more than forty years of age was much higher than that reported for a series of nondiabetic patients of the same age. Our study revealed that the incidence of coronary sclerosis and arteriosclerosis of the extremities was higher among diabetic women than it was among nondiabetic women of the same age. The main reason for the higher incidence of serious vascular degenerative disease in the cases observed in the postinsulin era is the prolongation of life that results from the administration of insulin. This probably also accounts for the

TABLE III. POSTMORTEM FINDINGS IN CASES OF DIABETES MELLITUS OBSERVED IN THE PRE-INSULIN AND THE POSTINSULIN ERA AND IN A CONTROL GROUP OF FIFTY CASES IN WHICH THE PATIENTS DID NOT HAVE DIABETES

	No.	Postmortem findings and percentage of cases in which they were encountered							
		Atrophy of islets	Hypertrophy of islets	Hyalinization	Lymphocytic infiltration	Pancreatitis		Fibrosis	Fatty infiltration
						Interlobular	Interacinar		
Cases of diabetes observed 1914-1922	25	24	56	16	16	0	52	52	40
Cases of diabetes observed 1923-1937	176	44	48	39	5	8	50	48	71
Control group of cases	50	8	54	2	0	14	38	8	56

higher incidence of malignant disease and other diseases which commonly occur in the later decades of life. Carcinoma of the pancreas occurred with unusual frequency and the incidence of chronic disease of the gall bladder also was high.

Adenomatous goiter occurred in twenty-four cases. In six of the cases the goiter was classified as hyperfunctioning. Exophthalmic goiter had been diagnosed in three other cases. No significant findings were encountered in the pituitary body in the few cases in which this structure was examined. The number of cases in which the intracranial contents were examined was not representative.

Our results support the contention that certain lesions of the islands of Langerhans are suggestive but not conclusive in the pathologic diagnosis of diabetes mellitus. Our study also illustrates the inadvisability of generalization regarding any correlation of the microscopic appearance of the pancreas and the clinical severity or duration of diabetes. The microscopic study of the pancreas indicated that there was a relative increase in the incidence of atrophy, hyaline changes and fatty infiltration in the cases observed in the postinsulin era. These changes may well be considered dependent on the prolongation of life that results when patients are treated with insulin.

BRUCELLOSIS*

I. FISHER, M.D.
Ceylon, Minnesota

BRUCELLOSIS, a comparatively rare and little known disease of a few years ago, is gradually assuming an important and well recognized place in public health. The author well remembers that brucellosis was regarded as quite rare, a disease whose existence was considered only after most other diagnostic possibilities had been exhausted. Little did he expect to see ten cases within a period of eighteen months.

Brucellosis is still of minor importance to men practicing in cities where the milk supply is well controlled and where animal contacts are few. The importance of this disease is becoming more manifest to the doctor in farming communities, where, if the gradual increase of this disease is an indication, the incidence of Brucellosis will soon assume alarming proportions. The period of disability emphasizes the economic factor in this disease. Here lies the importance of more extensive public health control.

The history, etiology, and symptoms of brucellosis are common knowledge. The recognition of this disease occurred following the Crimean War and in 1863 Marston offered the first detailed description of "Mediterranean Remittent Fever." Bruce isolated the organism he named *Micrococcus melitensis,* by cultures from the spleen of a patient. The specific agglutination test was first offered by Wright and Semple in 1897. In 1904, the Mediterranean Fever Commission traced the disease to goats. Alice Evans, in 1918, found the Brucella and Bangs organisms to be the same.

This disease is caused by *Brucella melitensis, Brucella suis,* and *Brucella abortus,* depending on the variety found in goats, hogs, or cattle. The disease is spread rapidly from animal to animal with a complete lack of constitutional symptoms. The only manifestations of the disease are abortion and incomplete separation of the placenta. The organisms are found in lochia, products of abortion, urine, feces, and milk. Thus the avenues of spread are many. Some cattle with positive tests may not show other evidence of the disease. It has been estimated that 20 per cent of the cattle in the United States are affected. The lack of testing in hogs may account for the increased incidence of brucellosis among farmers and handlers of livestock. This lack of testing in hogs would also make the eradication of this disease among livestock all the more difficult—or well nigh impossible.

The incidence of brucellosis among handlers of livestock is much higher than might be expected. Pasteurization of milk for use as milk proper and milk products eliminates the possibility of spread through urban populations, except in those cases in which the milk supply is not so well controlled. In smaller communities pasteurization of milk is not carried out and therein lies one avenue of infection. The other avenues are the ones of paramount importance, however. The increase of the disease has come about in farmers, veterinarians, butchers, and livestock dealers. The possibilities for infection here are unlimited. Entrance to the body may come through breaks in the skin or by the oral route. Handling of abortion material in animals, of course, offers the richest field. Beattie studied a group of veterinarians, both students and practitioners. The incidence rose from zero in students who had not handled placentas to 26.2 per cent in veterinarians who had been in practice more than one year.

In 1922 the first epidemic of any importance in the United States occurred in Arizona. Since then the number of cases reported each year to the United States Public Health Service has increased. From only 112 cases in 1927, the number rose to 1,453 in 1930, and in 1937 to 2,497 cases. In Oklahoma the incidence has increased tremendously from two cases in 1930 to 431 in 1937. Only a portion of the cases are being reported since the chronic cases frequently go unrecognized. The reported deaths have not changed a great deal; 55 in 1930 and 58 in 1939. The only way to prevent further increase in infection is by control of the disease in animals. Cattle can be infected by varieties other than *Brucella abortus* and in similar manner can transmit the infection to man.

*Read before the annual meeting of the Southern Minnesota Medical Association, Red Wing, Minnesota, September 23, 1940.

Brucellosis is not a difficult disease to recognize if it is only borne in mind. This variety of clinical types, namely: (a) subclinical, (b) intermittent, (c) ambulatory, (d) relapsing, confuse the picture and it is for this reason that a great many cases go unrecognized. The incubation period averages about two weeks, though it may run from five to twenty-one days. The onset of the disease itself is generally insidious, but may be sudden. There is a progressive rise in fever with complaints of general malaise, chills, backache, abdominal pain, and weight loss. Examination may reveal only the fever, abdominal tenderness, leukopenia; and splenomegaly in about half the cases. Except for the aid of specific tests these signs and symptoms could be attributed to a number of conditions. Diagnosis may be confirmed by agglutination test, skin test, blood culture, and opsonophagocytic index. Of these the agglutination and skin test are carried out most easily. The agglutination test, as carried out by the State Board of Health, is considered by most authorities to be positive with an agglutination of 1.80 and upward. This positive reaction will occur within five to fourteen days of onset. The intradermal skin reaction is more valuable in those suspected cases in which the agglutination test is negative. This test is considered more reliable by some authorities. Huddleson, in a study of allergic skin tests on 8,124 individuals found 10.3 per cent to show allergic reactions indicating past or present infections. He felt that the agglutination test alone would fail to detect better than 80 per cent of these reactions. This skin test is carried out by the injection of a bacterial filtrate of Brucella origin, injecting .05 c.c. intradermally in the same manner as a Mantoux test. This test is also read in forty-eight hours.

These aids in diagnosis are especially important in the subclinical and chronic cases. Stress has been laid on the fact that many of the subclinical cases have been diagnosed as neurasthenia, a fact that is readily acceptable when one finds that the textbook description of neurasthenia fits that of Brucellosis, namely: exhaustion, insomnia, irritability, aches and pains. Brucellosis has also been confused with tuberculosis. The relationship between various orthopedic states and Brucellosis has been recognized for some time. Less than 10 per cent of all cases show a typical clinical picture for diagnosis.

The question of therapy has also been clarified considerably within the past few years. Among the various types of treatment suggested are artificial fever therapy, specific serum, intravenous dyes and sulfanilamide. The results from fever therapy have been none too encouraging although some good results have been reported both from the use of hypertherm and typhoid vaccine. Intravenous dyes have fallen by the wayside. Specific vaccine prepared from avirulent strains of *Brucella suis* or *abortus* has been used intravenously with reports of excellent results. Flippin reports the treatment of five patients with polyvalent antiserum, with good results in all five cases. He first tested the patients with 1 c.c. intramuscularly and if no reaction occurred in twenty-four hours, this was followed by six daily intravenous injections of 50 c.c. of serum given with 100 c.c. physiologic saline. This injection was allowed to take fifteen minutes time.

The most encouraging results in the treatment of Brucellosis have been reported by those using sulfanilamide and its derivatives. Some workers feel that the drug should be administered for one to two weeks after the temperature has become normal. It has been found that if therapy is discontinued too soon, relapse may occur. Improvement will begin to take place within three to eight days. Relapse has been reported two to three weeks after the interruption of treatment. Since Brucellosis is not a self-limited disease in a good many cases but may well continue into a chronic phase, therapy should be completely carried out. One author recommends short intermittent courses of sulfanilamide for two to three months after the fever disappears. Question might be raised as to the safety of this procedure.

Sulfanilamide was used in eight of the ten cases reported here.

In two of the ten cases triple typhoid vaccine was also used after use of sulfanilamide had been carried out for eight to ten days. After two bouts of fever these patients were returned to sulfanilamide therapy. The temperature soon dropped to normal and remained there. In five of these ten cases, it was found that the leukopenia became a mild leukocytosis after institution of sulfanilamide therapy. No differential counts were done. The white blood cell count after therapy was begun ranged from 8,400 to 14,000.

In one of the patients, sulfapyridine was substituted for sulfanilamide and used in the same manner as in the treatment of pneumonia. His temperature became normal within thirty-six hours and remained there. Sulfanilamide had been used for a period of eight days on this patient without any change in temperature.

Relapse was encountered in two of these cases. In one case relapse occurred twice, the first time two weeks after discontinuing sulfanilamide and the second time about three weeks after sulfanilamide had been discontinued. Temperature finally returned to normal and remained there. The sulfanilamide had been used for two weeks during each course of treatment. In this patient, the complaint of soreness and pain along the recti muscles was so severe, that some intra-abdominal lesion was considered. Soreness over the inguinal region persisted in this patient for six weeks after the temperature had returned to normal. Relapse in the second case was controlled more easily. Both patients eventually became afebrile.

All of the cases reported had definitely positive agglutination tests with dilutions ranging from 1:160 to 1:1280. In one case, that of a butcher claiming compensation, allowance of the claim as an occupational disease was made by the State Compensation Commission. All of the cases were acute, exhibiting a fever ranging from 101 to 103 degrees when first seen. The most common complaints were a feeling of chilliness and headache in the late afternoon and evening. Associated with these were symptoms of anorexia, malaise, aching, fever. Eight of the cases were handlers of livestock.

The only woman in the group was delivered of a healthy baby about fifteen months after the onset of fever. She too, had been treated with sulfanilamide. In the two patients who were neither livestock handlers nor milk drinkers, the source of infection could not be traced.

The local dairy was checked following the discovery of one case in town and it was found that out of a herd of thirty-two cattle there were twenty-one positive reactors to the Bangs' test. The fact that no other cases developed from this source is difficult to explain. Of course, as has been mentioned, many cattle may be positive reactors without having any other evidence of the disease. Mastitis with eventual contamination of the milk may not be present in many cases. Inasmuch as Bangs testing was not compulsory, suspected herds in only four of the cases were tested and found to contain positive reactors. In spite of the fact that they are well compensated for the loss of their stock, many of the farmers are none too coöperative. Only in breeding stock is careful testing being carried out regularly. The ease with which livestock is now transported, and the increased activities of traders and dealers, makes cross-contamination in herds a simple matter, and tracing of the source a more difficult one. The value of compulsory tuberculin testing in cattle is recognized by the farmer, but optional Bangs testing is not easily obtained.

Summary

1. Ten cases of Brucellosis are reported from a single small community within a period of eighteen months.

2. Eight patients were treated with sulfanilamide or sulfapyridine with good results.

3. There is an apparent increase in brucellosis among handlers of livestock.

4. More public health measures may be necessary to curb further increase in this disease.

SEMINAL VESICULITIS*

RAYMOND F. HEDIN, M.D.
Red Wing, Minnesota

THE importance played by the seminal vesicles in urogenital infections is not generally well understood. In recent years, the anatomical studies of the seminal vesicles and ejaculatory ducts made by McCarthy and his co-workers, and also the development of the instrument bearing his name have done much to establish a better knowledge of the pathology involved in seminal vesiculitis and to establish a rational method of treatment. Herbst and Merricks have done well to point out in their many excellent publications the satisfactory clinical results they

*From the Interstate Clinic, Red Wing, Minnesota. Read before the annual meeting of the Southern Minnesota Medical Association, Red Wing, Minnesota, September 23, 1940.

have obtained by catheterization of the ejaculatory ducts.

Almost all infections involving the prostate gland, both acute and chronic, also involve the seminal vesicles. The seminal vesicles depend on their drainage from the ejaculatory ducts which course through the substance of the prostate gland to empty into the prostatic urethra. Because of the close proximity of the seminal vesicles to the prostate it is not difficult to see how organisms causing prostatic infection traverse the ejaculatory duct and enter the seminal vesicles. Often in acute prostatic infections the prostate gland becomes edematous and engorged, thus mechanically occluding the ejaculatory ducts. In chronic infections the ducts often are not patent due to fibrous adhesions or purulent plugs. When these circumstances exist the seminal vesicles become distended with purulent material and are found wanting for adequate drainage.

Fig. 1. Abscesses of left seminal vesicle.

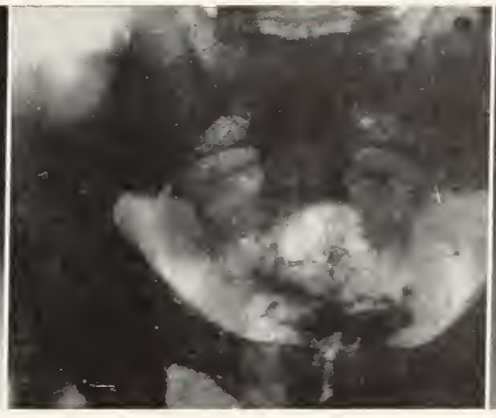

Fig. 2. Same patient as in Figure 1. Vesiculogram taken two months later. Drainage has taken place and massage given twice a week. Right seminal vesicle partially filled.

Fig. 3. Same patient after five months of treatment. Practically normal left seminal vesicle and vas deferens.

The organisms which most often cause seminal vesiculitis are staphlococci and colon bacilli. Undoubtedly these organisms, in many cases, come as secondary invaders to gonococci.

The symptoms of seminal vesiculitis are variable and depend, to some degree, on the amount of pus trapped in the seminal vesicles. Also the symptoms may be intermittent due to partial drainage of the seminal vesicles. Recurrent attacks of unilateral or bilateral epididymitis are pathognomonic symptoms. Indefinite, lower abdominal pain, backache or perineal pain, itching or a crawling sensation in the perineum may all be manifestations of infected seminal vesicles. Because of the close relationship of the seminal vesicles to the lower ureter, obstructive symptoms of the upper urinary tract may exist. Hemospermia may attract attention to the seminal vesicles as a source of infection. Sterility in the male can, at times, be explained by this type of infection.

Patients suffering from seminal vesiculitis often have had prolonged treatment by prostatic massage, urethral dilatations and instillations. The urine, perhaps, has been intermittently cloudy and clear, which, in some cases, indicates the amount of drainage from the seminal vesicles. Very often a patient will give a history of epididymal pain following massage. When the ejaculatory duct is plugged, massage churns up the infection and causes pus to travel down the vas deferens to the epididymis.

As was stated previously the method of treatment is one of adequate drainage. Vesiculotomy and vasotomy have now been replaced by transurethral catheterization of the ejaculatory ducts. This is accomplished by use of the panendoscope with the McCarthy attachment. This instrument permits small catheters or bougies to be introduced into the ejaculatory ducts. Through these catheters pus may be aspirated to determine the causative organism. It is not an uncommon experience after catheterizing the ejaculatory ducts to find pus emerging from the catheter. Also visualization of the vesicles is accomplished by injecting opaque media, such as diodrast, into the catheters and making roentgenograms of the vesicles. Such visualization gives one information as to the presence of abscesses in the seminal vesicles and, in some cases, the patency of the vas deferens. Medication such as silver nitrate

may be introduced through the catheter to lavage out the vesicles.

This procedure is carried out under local anesthesia of 0.5 per cent cocaine, or caudal block using 1 per cent novocaine. A panendoscope with the McCarthy attachment allows ureteral catheters to be directed down, back and inwardly into the ejaculatory ducts. Buckling of the catheters is obviated by introducing piano wire into the lumen of the catheters to give them support. The ejaculatory ducts are approximately 2.0 to 2.5 cm. in length. The arrangement of the ejaculatory ducts vary, depending on the depth of the utricle. In some instances it is difficult to ascertain which duct is being dilated before taking roentgenograms. To visualize the seminal vesicles 2 c.c. of diodrast is usually sufficient to inject into the catheter to obtain a satisfactory roentgenogram. The ejaculatory ducts are catheterized separately as it is not possible to insert two catheters simultaneously. Generally speaking, little or no reaction follows this procedure. However, it should be emphasized that it is usually necessary to dilate the ejaculatory ducts several times to establish adequate drainage.

Case Report

R. L., age twenty-nine, was first seen in January, 1940, complaining of recurrent attacks of bilateral epididymitis, backache and a crawling sensation in the perineum. He stated that the symptoms began six months previously. There was no history of gonorrhea. The urine was slightly cloudy and microscopically there were 8 to 10 pus cells per low power field. The prostate and seminal vesicles were rather soft, boggy and tender. A diagnosis of chronic prostatitis and seminal vesiculitis was made. Massage, twice a week, for a period of eight weeks gave no relief. In April, 1940, the ejaculatory ducts were catheterized and pus aspirated through the catheters. The seminal vesicles were visualized (Fig. 1), and dilatation of the ejaculatory ducts was carried out on several occasions (Figs. 2 and 3) at intervals of one month. The last vesiculograms appeared to be normal. The patient is symptom free except for a slight pain at times in his right epididymis.

Summary and Conclusions

1. Prostatic infection and seminal vesiculitis are closely associated.
2. The seminal vesicles depend on drainage from patent ejaculatory ducts.
3. Transurethral catheterization of the ejaculatory ducts with visualization of the seminal vesicles provides a means of determining the extent of disease present and allows drainage of the seminal vesicles.
4. A case which was successfully treated is reported.

◆ CASE REPORT ◆

AN INTERESTING CASE OF TRICHOMONAS VAGINALIS IN THE MALE

MAX HUHNER, M.D.
New York, New York

In most cases of trichonomas vaginalis in the male, either a urethral discharge or burning in the urethra at the end of urination and frequency of urination are present and it is these symptoms which cause the patient to seek medical advice.

In the case to be reported none of the above-mentioned symptoms were present, in fact, the patient never knew that he had this infection, but came on account of sterility. A routine examination of the prostatovesicular secretion obtained by massaging the prostate and stripping the seminal vesicles showed numerous live typical trichomonas vaginalis.

The patient was a dentist who did much x-ray work without any protection of his testicles. He was referred to me on account of sterility. He had been married three years, and his wife had had a child with a previous husband about seven years ago. He also complained that emission comes some time after orgasm, otherwise his coitus is normal. A condom specimen was examined about four years ago, and he was told that it showed motile spermatozoa but he did not know whether the number of spermatozoa was normal. His penis, testicles and prostate appeared normal to palpation. The expressed fluid however showed some spermatozoa most of which were dead and those that were alive showed only feeble motility.

HISTORY OF MEDICINE IN DAKOTA COUNTY

Biographies

(Continued from January issue.)

O. A. Beal located in West Saint Paul about 1896. He had previously practiced in Saint Paul. He was a graduate of Long Island College Hospital (1882). He served as a county physician for Dakota County.

J. G. Bemis came to Farmington from New York City in the fall of 1867. It is uncertain how long he practiced there.

T. N. Berlin was a homeopathic physician of Empire where he located in the latter sixties.

Robert Blakeley was the first practicing physician in Nininger Village, according to the county history by Franklyn Curtiss Wedge.

J. D. Brundage came from Naugatuck, Connecticut, and practiced in Hastings and in Lakeville toward the end of the seventies.

J. P. Caldwell was born in Illinois in 1848. At the age of sixteen he entered the army and served until the end of the war. He graduated from the Bennet Eclectic Medical College in 1874 and a few years later he came to Minnesota. He practiced medicine in Lakeville from 1882 until 1889, when he moved to Saint Paul.

Charles Cappellen, formerly of Brandon, Minnesota, opened an office in Hastings in 1899. He had the habit of advertising, modestly but persistently, in the newspapers.

R. E. Cavanaugh was graduated from Rush Medical College in 1894 and practiced in Hastings the following year.

F. D. Chapman, a homeopath, came to Hastings in 1870.

W. H. Cooke located in Lakeville in 1891. He served several terms as a county physician and as coroner. He was a graduate of Queen's College, Kingston, Canada (1888).

D. J. Cummings graduated from the Chicago Medical College and came to Farmington in the fifties. His professional card appeared in the *Dakota Weekly Journal* in June, 1856, but he may have come earlier. In 1871 he reported a case of leprosy which created considerable excitement in the locality. He later practiced in Hastings, Waseca and Northfield for short periods and then returned to Farmington in 1877. He was instrumental in the organiza-

tion of the Dakota County Medical Society and was an active member of both that and the state society.

J. Davidson, an eclectic physician, practiced in Hastings in 1868.

A. C. Dockstader, a homeopath, graduated in 1880 from Hahnemann Medical College and located at South Park, Dakota County. He practiced at various times in Granite Falls, Red Wing (1886), Minneapolis (1887-1889) and Saint Paul (1892-1896). The intervening periods were spent at South Park, Dakota County. He served as a county physician.

Levi P. Dodge was born in Sunapee, New Hampshire, in 1839. He was left an orphan at the age of six months and cared for himself from the time he was eight years old. At the age of twenty-two he began to study medicine with Dr. S. M. Whipple of New Hampshire. He enlisted in the New Hampshire Volunteers in 1861 and was given a position as hospital steward. He was at the second battle of Bull Run, Antietam and Fredericksburg but was discharged in 1863 because of ill health. He received a diploma from Dartmouth the next year and after practicing in New Hampshire for a short time he came to Farmington in 1865. His professional card, typical of the early physicians, announced that calls would be "promptly attended to, whether by day or night and 'no postponement on account of weather.'" He was a charter member of the Dakota County Medical Society, serving as president in 1878, and a charter member of the Minnesota State Medical Society. He was a member of the school board of Farmington for twenty years and served also on the board of control for the state public schools for dependent children. His death occurred in September, 1893, following an operation for cancer of the bladder.

William M. Dodge began to practice in Farmington about 1894. He often served as a county physician.

W. R. Endris of St. Louis practiced in Hastings in 1887.

F. B. Etheridge located in Hastings in May, 1860, having had, according to his professional card, thirty years' experience in his profession. During the war he was a surgeon with the rank of major in the Fifth Regiment of Minnesota Volunteers. He was taken prisoner near Corinth, Mississippi, and returned to Hastings in 1862 to resume his practice. He served as county physician, was a charter member of the county medical society and became affiliated in 1870 with the state society. He died in 1874.

J. H. Etheridge was a professor of Materia Medica and Medical Jurisprudence at Rush Medical College in 1869. The newspapers refer to him as being "formerly of Hastings." He died in Chicago in 1899 of heart disease.

Warren C. Eustis was born in 1847 in Boston, Massachusetts, and in 1855 moved to Minnesota with his parents. He attended the state university and was one of its first graduates. He received his medical training at the University of Michigan and the Bellevue Hospital Medical College, from which he obtained his diploma in 1877. He practiced in Farmington until 1891 when he moved to Owatonna and specialized in eye and ear work. He was a versa-

tile linguist, being able to converse with his patients in English, German, Norwegian, Danish and Swedish. He was a member of the Dakota County Medical Society, the Steele County Medical Society and the state medical association.

C. A. Faulkner practiced in Rosemount in 1900 and was in that year appointed county physician. He was a graduate of the Bennett Eclectic Medical College.

A. A. Finch began practice with his father, J. E. Finch, in Hastings in 1891. In 1894 he opened an office in Rosemount and divided his time between that town and Hastings. Shortly afterwards he moved to Blooming Prairie. He was a graduate of the University of Minnesota and had received his medical training at the University of Pennsylvania (1891). He was elected Dakota County coroner in 1892. He was a member of the National Association of Railway Surgeons, the pension board, and the Steele County Medical Society.

Jeremiah E. Finch was born in Ontario in 1829. He came to Hastings in 1856 having previously practiced in Illinois and Wisconsin. In 1862 he was appointed a surgeon with the rank of major in the Seventh Minnesota Infantry and the next year he returned to Hastings where he became one of the leading practitioners. He ran a drug store which he established early in the sixties and which later was known as Finch and Son. He was a member of the local hunting club, a Mason and a Knight Templar. In 1866 he was elected mayor of Hastings and he served a long term as the president of the Hastings school board and in other public offices. He was one of the first members of the county medical society organized in 1870 and served as its president in 1875 and in 1876. He was a charter member of the Minnesota State Medical Society and its president in 1878. In 1886 he was appointed physician for the Chicago, Milwaukee and Saint Paul Railroad.

Julius C. Fitch, a graduate of Rush Medical College (1866), was one of the early physicians in Hastings. He was among the first members of the county medical society and served as county physician, health officer for Hastings, and president of the Hastings school board. In 1871 he was elected to membership in the Minnesota State Medical Society.

Thomas Foster, a pioneer physician in Dakota County, was a man of varied abilities. He visited Olive Grove, the present site of Hastings, in 1850 and the next year built a home for himself which, excepting the trading station, was the first house in that vicinity. In 1852 he was appointed physician to the Sioux Indians. He was the editor of a newspaper, the *Minnesotan,* published first in Hastings and later in Saint Paul and Duluth. Besides practicing medicine he also was state librarian, a member of the constitutional convention, and private secretary to Governor Ramsey under both territorial and state administrations.

Doctor Foster was born in Philadelphia in 1818 and died in San Francisco in 1903.

C. P. Fuller came to Hastings at the age of fourteen. He entered the drug business and continued in it until about 1869 when he went to Philadelphia to study medicine. Returning to Hastings he again followed the drug business until the fall of 1874 when he went to Granite Falls, Minnesota, to prac-

tice. He died of gangrene poisoning in August, 1879, at the age of thirty-nine. He was a member of the Dakota County Medical Society.

W. W. Furber, a graduate of Rush Medical College, practiced in partnership with Dr. C. P. Adams in Hastings from May, 1878, until August, 1879. He later practiced in Cottage Grove, Washington County. He was elected to the Minnesota State Medical Society in 1878.

William Gibson practiced in Hastings in 1856.

R. F. Goodwin practiced with Dr. C. P. Adams in Hastings in 1869 and later moved to Cannon Falls, Goodhue County.

Elizabeth Graves was legally authorized to practice under the "years of practice act." She lived in Hastings during the eighties.

James Gravelly, a German physician from Iowa City, Iowa, came to Hastings in 1887. Apparently he did not stay long. Two years later he was in Young America. He was graduated from Iowa State University in 1887.

Henry Hahn located in Hastings in 1884. He practiced under an exemption certificate and previously had lived in Young America. In 1887 he served as city health officer and as county physician. The following year he opened an office in Saint Paul and several years later moved to Saint Cloud.

E. W. Hammes was born in Wisconsin in 1854. He graduated with honors from Rush Medical College in 1882 and practiced at New Trier and at Hammond in Dakota County. In 1900 he went to Chicago to take some postgraduate work. He served several years as a county physician. About 1926 he retired from practice and moved from Dakota County to Saint Paul. He died in October, 1934.

E. Hammond was born in Connecticut in 1819. He went to River Falls, Wisconsin, in 1855 and two years later came to Waterford where he lived on his farm, with the exception of two years spent in Minneapolis, until his death.

A. H. Hanchette was one of the pioneers of Hastings. He was an eye and ear specialist, according to his card, and was for a time associated with Dr. Wm. Thorne. He was elected the first mayor of Hastings in 1857 but resigned from the office and soon after left for the East. In 1864 he served as geologist for the State of Minnesota.

G. H. Hawes was born in Massachusetts in 1832 and in 1855 came to St. Anthony, Minnesota, where he engaged in mercantile pursuits and the lumber business until about 1866, when he began to study medicine with Dr. C. G. Higbee of Red Wing. He graduated from the Hahnemann Medical College of Chicago and after three years of practice in Iowa, located in Hastings in 1876, where he became one of the leading homeopathic physicians. He served as secretary of the Minnesota State Homeopathic Institute in 1881 and 1882. He died in 1892 of cancer of the mouth and throat.

A. B. Hawes of Hastings was graduated from the Hahnemann Medical College in 1890 and located at Elk Point, South Dakota. In 1892 he returned to Hastings and took over the practice of his father, Dr. G. H. Hawes, during the latter's fatal illness. He remained somewhat over a year. He was a member of the state homeopathic society.

V. J. Hawkins practiced in South Saint Paul and served as a county physician for Dakota County in 1889. He was a graduate of Rush Medical College (1881). He now resides in Saint Paul.

P. A. Heitz was born in Germany in 1820, received his medical degree in 1846 from the University of Heidelberg and practiced there until his coming to the United States a year later. He spent one year in Ohio and practiced for a while in Hannibal, Missouri. He was a member of the Marion County Medical Society (Missouri) and vice president of the State Medical Association of Missouri. He came to Hastings in 1880 where he was for a while collector of assessments for the Detroit Mutual Benefit Association. He served as county physician and finally established himself as one of the leading practitioners of the town. He was elected to the Minnesota State Medical Society in 1883. In 1886 he moved his office to West Saint Paul. His death occurred in Saint Paul in 1888.

Joseph George Hodgkinson was born in Ontario, Canada, in 1845. He was graduated in 1879 from the Detroit Medical College and he also attended the medical college of the University of Michigan. From 1880 to 1882 he was treasurer of the Pension Board of Examining Surgeons at Detroit, Michigan. The following year he came to Saint Paul where he attended the Saint Paul Medical College. He practiced at Battle Lake, Taylors Falls, St. Croix Falls, and Saint Paul. In 1895 he opened an office in South Saint Paul. In 1897 and 1899 he served as a county physician.

Hartland C. Johnson came to Farmington from Northfield in 1885. He graduated from the Chicago College of Physicians and Surgeons. He later moved to Saint Paul.

W. F. Kertson practiced at Mendota in 1886 and 1887. He was a graduate of the medical department of the University of Victoria, Canada (1882).

L. M. J. Leonard came to Hastings in 1870 from Kenosha County, Wisconsin.

R. L. Marvin was one of the pioneers of Hastings. He came in the early sixties and ran a drug store for many years. In 1875 he was elected to membership in the Dakota County Medical Society and served as both secretary and treasurer of the organization for several years.

W. W. Memminger practiced in Rosemount in 1899 and served as a county physician.

C. F. Miller practiced in Hampton in 1899.

A **Dr. Munson** practiced at Pine Bend near Inver Grove during the latter sixties and early seventies.

A **Dr. Nichols** practiced with Dr. C. C. Righter in Hastings in 1863, having previously practiced in Prescott. This may be the same as the Dr. Ziba Nichols who was also in Dakota County in the sixties.

A. G. Phelps was a homeopath who practiced in Hastings in the latter nineties. He was a member of the state homeopathic society.

Horace Phelps, according to Neill and Williams' history of Dakota County, came to Lakeville in 1856.

T. G. Potts came to Castle Rock in 1856 and practiced there until 1863.

C. C. Righter, a homeopathic physician, located in Hastings in 1862. About 1868 he went to Faribault for three years and then, after another period in Hastings, again went to Faribault in 1879.

Peter Schneider began practice in Hastings about 1890. In 1894 and 1895 he was very active in the office of city health officer. In 1897 he received a diploma from the Wisconsin Eclectic Medical College. After a trip to Germany in the summer of that year, he moved to Saint Paul.

F. P. Shillock (*see* History of Medicine in Carver County).

J. Dennis Smith, a graduate of the University of Pennsylvania, came from Philadelphia in July, 1870, to practice in partnership with Dr. C. P. Adams of Hastings. He was one of the charter members of the county medical society. He returned to Philadelphia in 1871.

Jenks S. Sprague was born in Otsego County, New York, in 1800. He graduated from the College of Physicians and Surgeons of Western New York and after practicing in Schoharie County for a few years he became a partner of Dr. Naboth Buckingham of Exeter, with whom he had formerly studied. In 1854 he returned to Otsego County where he remained until 1863 when, his health failing, he came to Hastings, Minnesota, to retire from active practice. In 1854 he served as president of the New York Medical Association and was greatly influential in legalizing the practice of dissection in that state. He was also a member of the American Medical Association and a member of the New York state legislature (1853). He served as president of the Dakota County Medical Society from the time of its organization until 1874 and was the first honorary member to be elected to the Minnesota State Medical Society. The many positions of honor which he held bear witness to the esteem in which he was held both as a physician and as a man.

Otto Stannis, a homeopathic physician, located in Hastings in 1859. He had received his education in Germany and had practiced in both that country and this before coming to Minnesota.

A **Dr. Straussman** divided his time between Hastings and Stillwater in the latter seventies. His qualifications as a physician are unknown.

Wilfred O. Tessier was graduated from the College of Physicians and Surgeons, Minneapolis, in 1887, and located at Mendota. He opened a drug store there in 1889.

William Thorne, one of the well established and one of the oldest practicing physicians of Hastings, was born in Devonshire, England, in 1820. He came to New York State in 1834, studied with several physicians and took a preliminary course of lectures at Buffalo College in 1847. After practicing for a year and a half he returned to Buffalo and received his degree of Doctor of Medicine in 1850. In 1856 he came to Hastings where he established a drug store. He was one of the first members of the county medical society, of which he was president in 1874 and in 1877, and also a charter member of the Minnesota State Medical Society. He served several terms as county physician and was a member of the pension board. About 1899 he and his wife moved to Covina, California.

A **Dr. Thompson,** a graduate of the University of Pennsylvania, for a time in the late fifties was associated with Dr. Thorne of Hastings. He also practiced for a time at Hudson and Superior, Wisconsin.

W. H. Thurmond, a physician from Dowville, Iowa, practiced in Rosemount in 1879. About 1881 he moved to Brownton, McLeod County, and then to Athens, Georgia (1885).

A **Dr. Torgerson** was a practicing physician in Empire in 1868. He also ran a dry goods store.

James M. Tucker began to practice in Hastings about 1886. He was an enthusiastic member of the Loyal Legion and the G. A. R. and filled various offices in the latter organization. He served as health officer in Hastings for several terms, and for many years was a county physician. He was also appointed to the pension board (1891). He was a member of Company E of the National Guard.

Henry Van Beeck opened an office in Hastings in 1889, two years after his graduation from Rush Medical College. He was elected county physician and health officer for several terms. He also served as coroner and as a member of the pension board. He was affiliated with the State Medical Society.

H. D. L. Webster, a homeopath, came to Hastings to practice in 1867. Previously he had practiced in Winona and a year later he moved to Little Rock, Arkansas.

Robert L. Weems, physician and surgeon, came to Hastings in 1867. For many years he ran a drug store there. He was a charter member of the Dakota County Medical Society.

J. M. Whipple came to Hastings in 1857. According to his professional card he specialized in ophthalmic surgery. He also sold drugs and medicines.

Thomas S. Williamson (*see* "The Missionary as Practitioner," Minnesota Medicine, October, 1940).

William Willson was a practicing physician in Hastings in 1868.

(To be continued in March issue.)

President's Letter

YOUR COMMITTEE APPOINTMENT

THE Minnesota State Medical Association is made up of approximately two thousand six hundred members working through a setup which calls for officers and committees. These committees are again subdivided into scientific, non-scientific, and those on medical economics; as fine a democratic enterprise as can be found in any organization of a similar nature.

These committees cover every phase of economic and scientific endeavor in which medical men can be interested, and to be appointed to a committee should be, and can rightly be, considered an honor. But such honor is of no value unless a man feels the necessity of lending not only his support but his presence at committee meetings. The Association needs every man's constructive view in committee deliberations, especially in these momentous times. Once a man gets into the swing of medical thought in this state, he will miss the enthusiasm of committee contacts if unable to attend.

Medical education is not only undergraduate but must continue through a medical man's entire professional life as shown recently in the deliberations of the Committee on Child Health, when there was a thorough discussion of the plan for the course on The Problems of the Premature and Unborn Infants at the University. An enthusiastic committee meeting with much constructive thought resulted.

The survey of human tuberculosis and its follow-up in Meeker County, Minnesota, was outlined under the supervision of the Committee on Tuberculosis at their monthly meeting with the physicians of the locality in Litchfield. When completed, this will bring national recognition and be of untold benefit to the people of our state.

That we are vitally interested with the Minnesota Safety Council in the prevention of accidents, especially those of motor vehicles, was brought out forcefully at the annual meeting of this Council when it was shown that heart disease, 24.7 per cent, cancer 13.6 per cent, and cerebral hemorrhage 8.5 per cent, are followed a close fourth in Minnesota by accidents, 7.7 per cent, as the cause of death. Our Committee to Study Motor Vehicle Accidents can well be an integral part of their state-wide setup. Preventive surgery is its aim.

Outside of organized medicine, but still a very closely affiliated corporate part, is the National Physicians' Committee for the Extension of Medical Service. It is fundamental that we recognize immediately the need of supporting this committee in its work of acquainting the public with the gains in medical practice and the necessity of the patient-physician relationship as against state controlled medicine. An investigation of its work not only makes one enthusiastic about but a financial supporter of this worthwhile endeavor.

An exchange of ideas in local societies will soon wear away the barrier of indifference and each individual, as well as the society as a whole, will be the gainer; but each one should attend his committee appointments without fail. Democracies are controlled by the associational ideas which are freely given in committee or other similar bodies deliberating for the good of the whole. There is something of interest happening which you lose by not attending. Your committee chairman and the officers need your help as well as criticism. Dictators or inside cliques will find no place in any association where well functioning committees are found.

TREACHEROUS TUBERCULOSIS

ATTENTION is called to an article by Laird in this number of Minnesota Medicine which merits emphasis aside from the Malmros-Hedvall concept described therein.

It is another appeal for the detection of early tuberculosis of the lungs, pointing out again that contacts furnish the richest source of potential disease. It is a warning that beginning tuberculosis in the main produces no symptoms. It demonstrates how frequently these early, symptom-free lesions may go for months to a year or more before giving symptoms. It teaches that in many instances there are no distinctly differentiating characteristics between primary phase tuberculosis and reinfection phase tuberculosis and that most certainly all primary phase lesions are not benign as many observers have been insisting.

It is also clear from the material which Laird presents that, as in the treatment of pulmonary tuberculosis so in the correct clinical interpretation of the early latent lesion, time is the essence of the contract as prolonged observation is often necessary.

Two additional points may well be stressed. First, that not infrequently outspoken clinical disease may develop in but a few weeks subsequent to an initial infection. This occurs not only in infants but in adults as well. Second, that some of these minimal reinfection phase lesions with no treatment will disappear or fade out to the point of becoming fibrous, strand-like areas.

Finally, it should be reiterated that this and similar papers clearly demonstrate that we are in an era when by going out and searching for tuberculosis we are encountering problems which are new, requiring judgment of the highest order from the practising physician. It is distinctly another period in the fight against this insidious, treacherous and unpredictable disease.

—E.K.G.

VENEREAL PROPHYLAXIS

IN HIS autobiography, reviewed elsewhere in this issue, Hugh Young tells the intimate details of the way in which, for the first time in the history of warfare, a serious and effective attempt was made to control the incidence of venereal disease among the troops. It is a fascinating story of careful planning by a master mind backed by competent authority.

Young went to France with the first military contingent from the United States, six weeks after we entered the war. General Pershing and his staff were on board and from first to last the Commander-in-Chief gave his unstinted support to Young's proposals. Everyone knows the result. Venereal disease in the A. E. F. was held to a minimum throughout hostilities, an unparalleled record in military history.

Hugh Young has done many things of importance in his long and useful career but nothing

he has ever accomplished bears any comparison, for far-reaching benefit, to his skill and persistence in carrying out his ideas in the prevention of venereal disease. It furnished an example for the whole civilized world of what could be done by carefully applied scientific knowledge, properly enforced.

Now that we are again mobilizing a large force, regardless of whether war comes or not, it is to be devoutly hoped that the lessons of 1917 and 1918 will be clearly remembered and utilized. Anything less will be a disgraceful reflection on our national intelligence.

GILBERT COTTAM

SULFATHIAZOLE

JUST a year ago we published an editorial entitled "Sulfapyridine and Pneumonia"* calling attention to the value of sulfapyridine in the treatment of pneumonia, but concluding that this dye "is doubtless not the last word in chemotherapy for this infection." The reports of the use of another dye, sulfathiazole, in pneumococcic pneumonia, indicate that this drug is just as efficacious in the treatment of this infection and has distinct advantages.

According to reports, sulfathiazole is more rapidly absorbed and is more rapidly excreted than sulfapyridine, some 80 per cent of a single dose being excreted by the kidney in twenty-four hours. Its action on the pneumococcus *in vitro* and clinically, seems fully as great as that of sulfapyridine. Its rapid absorption and excretion doubtless account for the greater difficulty in obtaining a high concentration in the blood, but, clinically, a blood concentration of 5 mg. per cent seems sufficient for therapeutic results.

Sulfathiazole, too, is only about half as toxic as sulfapyridine. This is shown by the less frequent appearance of vomiting and malaise which is a distinct drawback to the use of sulfapyridine. Skin eruptions, however, in the form of a maculopapular eruption most prominent over the extremities is paradoxically more frequent with sulfapyridine. An eruption resembling erythema nodosum has been described in a few cases. One author has called attention to the danger of kidney damage from the intratubular recrystallization of the dye in the kidney. This must be of rather rare occurrence with the customary administration of the dye, for hematuria rarely occurs. This possibility, however, offers a warning against large or prolonged dosage and too little liquid in the diet.

The dosage of sulfathiazole is similar to that of sulfapyridine. Two grams can be given as an initial dose, and 1 gram every four hours for twenty-four hours, when the dose should be reduced and then stopped after five to seven days.

So startling have been the results from this use of sulfathiazole in pneumococcic pneumonia that the need for specific serum in conjunction has been cut to a minimum. As a matter of experience the administration of this dye has often interfered with typing and made specific serum administration impossible.

Sulfathiazole has proven itself the outstanding dye in the treatment of staphylococcic infections. Remarkable results in the treatment of staphylococcic septicemia have been reported. It has also proven itself of great value in urinary tract infections in which the staphylococcus Bacillus proteus, alpha hemolytic streptococci and Escherichia coli are present.

It is perhaps useless to warn against expecting the impossible from this valuable dye. Surgical principles should not be lost sight of and nursing and medical care are still important. The occasional occurrence of hematuria and anemia from the use of the dye affords a warning against its careless use.

It would not be too sanguine to predict that further advances in chemotherapy may be expected.

*Minn. Med. 23:124, (Feb.) 1940.

CONTRARY LAWS

Two contrary laws seem to be wrestling with each other nowadays; the one a law of blood and of death ever imagining new means of destruction and forcing nations to be constantly ready for the battlefield—the other, a law of peace, work and health, ever evolving new means of delivering man from the scourges which beset him. The one seeks violent conquests; the other, the relief of humanity. The latter places one human life above any victory; while the former would sacrifice hundreds of thousands of lives to the ambition of one. The law of which we are the instruments seeks, even in the midst of carnage, to cure the sanguinary ills of the law of war; the treatment inspired by our antiseptic methods may preserve thousands of soldiers. Which of these two laws will ultimately prevail, God alone knows. But we may assert that science will have tried, by obeying the law of humanity, to extend the frontiers of life.—LOUIS PASTEUR.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

THE CASE FOR THE DOCTORS

Any honest effort to economize, such as that set in motion in our state government, is applauded by physicians; but it may on occasion overstep the mark and require special adjustments.

Representatives of the Minnesota State Medical Association, while heartily favoring reductions in state expenditures wherever possible, are generally agreed that reductions, in the interest of economy, in the salaries of physicians serving in state institutions would seriously endanger the high standards of medical care always upheld in these institutions. Heads of the institutions, themselves, have become alarmed at reductions proposed last year and have vigorously protested.

Members of other professions have likewise been affected by the reductions and these also have made representations to the authorities. The result was the appointment of a Committee of the Legislature to investigate the situation and make recommendations. Testimony was presented by representatives of the physicians, lawyers, dentists, engineers, laboratory and social welfare workers. The case for the medical profession follows:

Course Is Long

To prepare a physician for practice a longer period of time is required, on the average, than for any other profession. As much or more preliminary college work is required of him before he enters medical school and the medical school course itself is as long or longer than that of any other professional school. A professional degree granted at the end of the course entitles virtually all other professional men to enter immediately upon the practice of their professions; but for the physician an additional year of internship, at the very least, must be fulfilled before he receives his degree and a license to practice medicine. For many men, furthermore, the degree of M.D. is only a stage in their preparation for practice. If the physician wishes to enter upon any specialty—and much of the practice in state institutions is specialized practice—he must have additional training and the minimum time required for such specialized study is almost standardized at the present time at three extra years beyond internship.

It is undoubtedly a fact, therefore, that the medical servants of the state have behind them a longer period of preparation at greater cost than any other group.

Responsibility Is Heavy

No doubt each of the professions could present a strong case for its own relative importance to the work of government but it is also a recognized fact, that, apart from training requirements, none carry with them the responsibility of life and death for the people under their care which the physician carries. Such responsibility weighs heavily on the man who carries it and added to it are irregular hours of work, an irregularity which does not to any great degree affect the other professions. There is also the fact demonstrated in all statistics about physicians that they enter late upon their life work and that it is terminated early. Often it is terminated prematurely by heart disease, that great affliction of physicians, or by early retirement made necessary by the strain and the exacting character of the work. Earnings should therefore, in justice, be adjusted to the length of the earning period.

Money Saved

The advantage to the state of a high quality of medical service is also worthy of careful attention. Aside from the benefit to the individual served there is a saving to the taxpayer that comes from the presence in the institution and

administrative divisions of well-trained men who keep abreast of scientific advancement. Thus the length of illness is reduced, proper regulations for segregation and admittance are maintained and expert advice is available in every phase of public health which in turn leads to reduction of illness and limitation of the institution populations cared for by the state.

In short, it was the opinion of the state association representative that both the public welfare and true economy call for employment of the highest type possible of medical service and that such service cannot be secured without reasonably adequate compensation for the physicians employed. Physicians as tax payers are well aware of the stress and strain of budget making and heartily endorse the desire of the administration to cut costs wherever possible but it was the reasoned opinion of the representative of the state association that both wisdom and economy call for employment in state institutions and departments of the highest type of medical service obtainable.

Pivotal Function

It is obvious, apart from the public interest, that the private welfare of the entire profession is involved in this matter. Standards of compensation for any section of physicians tend to be accepted as standards for all. Furthermore, in virtually all health and welfare programs in the state, whether in the public health units, state institutions or in federal agencies, the doctor is the essential factor. His work is the pivotal function and should be recognized as such even in the matter of remuneration for his work.

PUBLIC HEALTH PROGRAMS INITIATED BY PHYSICIANS

While women's clubs, welfare organizations, congressmen and students were debating health needs of America in terms of costly legislative reforms in 1940, members of the Minnesota State Medical Association were quietly forging ahead in a campaign to see that every child in Minnesota is protected against smallpox and diphtheria. Also they were laying the foundation for what may be an experiment of world-wide significance in the area control of tuberculosis in the human population.

These two projects, conceived and sponsored by the practicing physicians of the state, will cost the state government nothing except the funds already appropriated to the State Board of Health for vaccines and toxoid and, as the tuberculosis project gets under way, for laboratory examinations and treatment already provided in our State Division of Epidemiology and our system of sanatoria for the tuberculous. As they progress, they are certain to save the state untold amounts in money and in the lives of citizens.

The two projects, sponsored and pushed by committees of the Minnesota State Medical Association, were reported in detail at the December Council Meeting of the Association and they afford an apt illustration of what the physician means by a public health program for America, in contrast to the grandiose legislative proposals of non-medical reformers.

Attack Realistic

Both represent a realistic attack upon definite problems, by tested methods, at modest cost and within the existing organization of medical and public health services.

Community vaccination and immunization programs carried on by the physicians who practice in the community are not new in Minnesota. Heretofore, however, they have been carried on in a somewhat sporadic and unorganized fashion. In some counties they have been well organized and have been for some time a routine part of the health services of the community. In others, little consistent effort has been made to reach all of the children and particularly the preschool children in a community effort.

Immunization Campaign Launched

At the direction of the Council last year, and with the coöperation of the State Board of Health, a packet of approved material, including the latest information from authoritative sources on administration of procedures, and also practical information as to aid available from the State Board of Health, three approved plans for carrying on a community program and specimen organization material, such as consent cards and records, were assembled and sent to every medical society secretary and members of all contact committees of the state. Every society was urged to set in motion a medically sponsored plan for its own community if such a plan was not already in active operation.

The result was immediate. Some 35 counties and communities in the state were carrying on

immunization or vaccination programs or both —or were in process of organizing such plans before the end of 1940. More toxoid had been distributed by the Board than in any other year since the state made immunization material available to the physicians of the state and demands for toxoid and vaccine were in danger of exhausting the supply allowed for the purpose in the budget of the Board.

The program under state medical association sponsorship has only just got underway, of course, and further development may be expected during 1941. New impetus will be added, furthermore, by a new and valuable aid just made available through the efforts of the Board in coöperation with the state medical association.

Nursing Aid Available

This new aid takes the form of expert public health nursing service which can be secured to aid physicians in communities where no public health nurse is now employed to carry on the program.

Two nurses have now been made available by the Board for this purpose. Plans for the most effective and economical use of their services are now being drawn up by state medical and health department officials and will be sent direct to county medical society officers within a few days. According to preliminary plans, these nurses will be able to spend a period of approximately two weeks in the community aiding in preliminary organization and possibly in the actual administration of procedures depending upon the local need.

Experiment Started in Tuberculosis Control

The tuberculosis project has a spectacular quality which brought it headlines and front page space in the preliminary public announcement made just before the first of the year.

At the suggestion of the Council the Committee on Tuberculosis has worked out a unique plan for tuberculosis control in the human population of one Minnesota county. This plan is a copy with reservations of the methods used so successfully by veterinarians in eradication of tuberculosis among cattle. Meeker county was chosen for this experiment and if the experiment there is a success, it will be extended to other counties in the state with the ultimate objective of certifying Minnesota for human tuberculosis in much the same fashion as it is now certified for eradication of tuberculosis among cattle.

The success of the veterinarians has for some time constituted a challenge to experts in human tuberculosis. They have felt that here was the key, pending the possible discovery of an effective chemical attack on the disease, to the control of tuberculosis in the human family. But it remained for a committee of physicians to take the first bold experimental step in Minnesota. In getting the experiment under way, the physicians will not go to the legislature and ask for sweeping new authorities and appropriations. In fact, the initial small fund necessary to set administrative machinery at work has already been appropriated by the Council of the association. They will start with a conception new to human tuberculosis control, the area conception of control, and they will work quietly and modestly in one county, first making careful records, using education rather than coercion and, if the time comes when government assistance is needed to put a wider plan into effect, they will be ready with the experience and figures to guide it. This is a typical example of the ideals and methods by which physicians work to conquer disease and improve the health of the people.

Meeker County Chosen

Choice of Meeker county for the experiment is of historical as well as practical interest. It was in Meeker county in 1923 that the first tuberculin testing of cattle on a county-wide basis was undertaken in Minnesota.

Inspired by Dr. Charles E. Cotton, State Veterinarian, who, in 1892, participated in the first tests made on cattle in the United States, the Minnesota Live Stock Sanitary Board entered into a coöperative agreement with Meeker county for compulsory testing of cattle under the area plan in May of that year. A legal battle followed which gained international attention. It was waged and won by Meeker county farmers for the new method. The result was that, in 1925, Meeker county became the first in the world to earn the "Accredited" rating, which means that less than 0.5 per cent of cattle in the county reacted positively to the tuberculin test. By 1935 the entire state of Minnesota had achieved the accredited rating, a remarkable record in disease control.

Meeker county also figured in a pioneer survey

of tuberculosis in the human population carried on there and in four near-by counties by Dr. H. G. Lampson of the State Department of Health in 1912. This survey gave rise to a strong and continuing interest in the tuberculosis problem among physicians of the county and these physicians have now volunteered their services in this new attempt to conquer tuberculosis in Meeker county.

Lay Assistance Sought

Every resident of Meeker county will be offered the tuberculin skin test and all possible means of persuasion will be used to secure widespread acceptance of the invitation. The test will be repeated, systematically followed by careful examination of positive reactors. Assistance of volunteer and lay agencies will be sought to aid in financing x-ray examinations for those who need assistance and in the campaign of education that will be necessary for the success of the plan. Full advice and coöperation will be sought from the State Board of Health.

WISCONSIN EXPERIMENTS ABANDONED: NO DEMAND

It is of interest to students of sickness insurance plans in Minnesota to note that the experiment in voluntary sickness insurance carried on for several years by the Douglas County Medical Society in Superior, Wisconsin, has been discontinued.

Reasons for abandonment are significant: first, that there was an exceedingly small demand for the plan; second, the cost of acquiring subscribers was extremely high; third, the plan did not reach those in the low-income group for which it was designed; fourth, operating costs, which included the new "middle man," were high; fifth, premiums were too small to permit payment of minimum standard fees for the community to the physicians while at the same time paying overhead costs and creating a necessary reserve.

Discontinuance of the trial plan in Milwaukee has also been announced for much the same reasons; likewise, the effort started some time ago to develop a plan in Rock County.

Superior Subscribers Insufficient

The following account of the Superior undertaking and its experience is reprinted from the January issue of the *Wisconsin Medical Journal* because of its importance to all who are interested in new methods for distribution of medical services and especially to those who have reported a great public demand for sickness insurance.

After contribution of over $3,000 in unpaid services by the members of the Douglas County Medical Society, and a contribution, to assist in defraying administration costs, of over $1,100 in cash by the State Medical Society of Wisconsin, the Douglas County Medical Society voted by ballot at its November meeting to discontinue its participation in the experimental voluntary sickness insurance plan of the Coöperative Health Association. The trial plan for prepaid sickness care which assured subscribers to the plan complete and unlimited medical care from their family physician through the payment of monthly dues varying from $1.50 to $2.90 per month had been in service operation for eighteen months. Prior to that time, the Coöperative Health Association had spent a number of months attempting to secure a sufficient number of subscribers (150) to permit initial operation of the plan.

The full-time manager and the executive committee of the Coöperative Health Association, after twenty-four months of intensive sales effort, were able to secure only 295 subscribers to the plan.

The Advisory Committee on Voluntary Sickness Insurance recommended to the House of Delegates that the experimental sickness insurance plans both in Milwaukee and Superior be discontinued at the termination of existing agreements. The House of Delegates, however, following an extended discussion of the plan by the Superior delegate, Dr. T. J. O'Leary, amended the committee's recommendation to provide that continuance or discontinuance of the plan should be governed by the wishes of the local county medical society affected. It is to be remembered that this plan for prepaid medical care is one which was designed by the Coöperative Health Association and subjected to a laboratory trial by the Douglas County Medical Society in order that the members of the local county medical society might assist the profession in Wisconsin in finding, if possible, a plan for the prepayment of medical care which was socially desirable, financially sound, and one which would be possible of enlargement in Wisconsin without incorporating the many inherent dangers invariably found in plans of this type and in the compulsory sickness insurance plans found in European countries. Neither the local county medical society nor the State Medical Society felt, after eighteen months of first-hand study, that this plan held any promise of filling these standards.

The sincerity and coöperation of the Douglas County Medical Society and the State Medical Society were complimented by the Coöperative Health Association through the chairman of its executive committee, Mr. Oscar Cooley, when he wrote to the coöperative societies as follows:

We wish to state also that our relations with the Wisconsin Medical Society and with the twenty-one

doctors on our panel are of the very best. They are giving us their wholehearted coöperation. We regret to have to state this but the fact is that we have received better coöperation from the doctors than we have from the rank and file of consumers.

FOR YOUR PROTECTION

(Monthly Editorial Prepared by the Medical Advisory Committee)

With the ever expanding Defense Program well under way, more and more physicians and surgeons are being called into the Army. There is every indication that within the space of a few months a large number from the State of Minnesota will leave private practice, and enter military service. This means that the practice of the man called into Army service must be turned over to someone else. It may be to one of his associates in his community, or it may be to a Locum Tenens.

If you are called into Army service, and turn your practice over to another physician, certain precautions should be taken for your protection as well as that of the physician who assumes the responsibility of your practice. Have your records up to date, and freely accessible. This includes clinical records, laboratory records, and x-ray records. The physician who takes your place must be able to familiarize himself with the history and findings of the patients whose care he undertakes in your absence. If you leave fractures in the course of healing be very sure that an accurate x-ray record is made of the status of this fracture when you turn over your practice to your temporary successor. If you have cases in the hospital, surgical or medical, be sure that the chart and record in the hospital, as well as your own record in your office, are brought up to date with an accurate description of the patient's condition when you leave the case. Introduce, personally, your temporary successor to all patients who are under active treatment when you leave. Explain to the doctor who relieves you just what you are doing in each case, and just what you think should be done with future treatment. A little time and attention to these details will protect both you and the doctor who relieves you.

In addition to the above, be sure to notify the company who carries your physicians' liability insurance that you are leaving, and inform them who is taking over your practice. If your temporary successor is a young man who has just finished his internship, or fellowship, and who has not had physicians' liability insurance in the past, advise him to get it at once upon assuming your practice. You cannot be too careful about this. While all companies writing physicians' liability insurance issue policies providing for broad coverage, there are many technicalities, and it is of great importance to you and your temporary successor that the insurance company understand what is taking place, and that you and your successor are informed by the insurance company that you are both fully covered.

Your Medical Advisory Committee feels that the year 1941 should see a decline in malpractice suits in Minnesota, and your Committee believes that this will be the case. The Committee realizes, however, that responsibility rests upon the individual physician, and earnestly advises your attention to the details outlined above.

W. H. H.

COUNTY OFFICERS' MEETING

Saturday, February 22, is the date selected for the annual County Officers' Meeting; the place is the Saint Paul Hotel.

This meeting comes at a time when physicians all over the state are pre-occupied with defense problems, either as examiners for the draft, as members of appeal and induction boards, as reserve officers in the medical corps, or as non-eligible civilians upon whom will rest the burden, sometimes under severe handicap, of caring for the cilivian population at home. An important section of program time will therefore be devoted to these special military medical problems with Lt. Col. R. B. Hullsiek, Director, Medical Division of the Selective Service System, and Major F. S. Richardson, Surgeon of the First Military Area, as speakers.

Mr. John B. Pratt of Chicago, executive secretary of the National Physicians Committee for Extension of Medical Service, will be luncheon speaker. He is expected to give emphasis to social and political phases of the defense problem, particularly to the dangers to the traditional American system of practice that may lie in

hasty and ill-considered emergency defense measures.

Another program headliner is Justice Royal B. Stone who will talk to the medical officers about the obligations and responsibilities of the doctor in court and particularly about the work of the newly organized Committee on Medical Testimony to which Minnesota jurists have been invited to send suspicious cases for investigation and possible discipline.

Relief, new state legislation, new state association programs including the immunization program, the subject-of-the-month program and the Meeker county project of the Committee on Tuberculosis will be discussed during the day; also such special secretary's difficulties as securing attendance at meetings.

The conference will open at 8:30 a.m. with round table breakfasts for informal discussion. Expenses will be paid, as usual, for one representative from each county and district society to attend the meeting. All members are invited to be present, however, and all will be guests of the Association at the luncheon at 12:15.

NATIONAL CONFERENCE ON MEDICAL SERVICE

The National Conference on Medical Service, to be held Sunday, February 16, at the Palmer House in Chicago, originated in Minnesota as the Northwest Regional Conference and has grown from a small meeting of medical officials in neighboring states to an important nation-wide gathering. The conference is now held annually in Chicago on the Sunday preceding the Annual Congress on Medical Education and Licensure, scheduled for February 17 and 18. Minnesota speakers on the program are Dr. W. A. O'Brien, director of postgraduate medical education at the University of Minnesota, who will talk about the medical program of the Center for Continuation Study, and Dr. A. W. Adson of Rochester, and Mr. Walter Finke of Saint Paul, director of Minnesota's Division of Social Welfare, both of whom will discuss Minnesota's system for medical care of social security clients.

The program is as follows:

Morning Session

Registration

VOLUNTARY GROUP MEDICAL CARE PROGRAMS

(1) "The Second Year"—Mr. J. D. Laux, *Executive Director, Michigan Medical Service, Detroit, Michigan*
(2) "Why Are We Waiting?"—W. M. Hartman, M. D., *Macomb, Illinois*
(3) "What We Learned From the Wisconsin Experiments"—Mr. J. G. Crownhart, *Madison, Wisconsin*
(4) Question and Answer Period

MEDICAL PREPAREDNESS

(1) Irvin Abell, M. D., *Louisville, Kentucky*
(2) Morris Fishbein, M. D., *Chicago, Illinois*
(3) Colonel Leonard Rowntree, M. D., *Chief, Medical Division, Selective Service System, Washington, D. C.*
(4) Olin West, M. D., *Chicago, Illinois*
(5) Question and Answer Period, conducted by Roy W. Fouts, M. D., *Omaha, Nebraska*

NOON-DAY DINNER

Afternoon Session

President's Address—Forrest L. Loveland, M. D., *Topeka, Kansas*

Report of Nominating Committee; Annual Election of Officers; Selection of place for 1942 Meeting.

STATE MEDICAL SOCIETIES' POSTGRADUATE PROGRAMS

(1) "A Rural State's Program"—H. E. Snyder, M. D., *Winfield, Kansas*
(2) "As Carried On in Minnesota; A Coöperative Program"—W. A. O'Brien, M. D., *University of Minnesota Medical School, Minneapolis, Minnesota*
(3) "The Illinois Program"—Robert S. Berghoff, M. D., *Chicago, Illinois*
(4) Question and Answer Period

LEGISLATIVE PROBLEMS

(1) Federal—E. H. Cary, M. D., *Dallas, Texas*
(2) State—Mr. J. W. Holloway, Jr., *Chicago, Ill.*
(3) Question and Answer Period; Conductor to Be Announced

MEDICAL CARE FOR SOCIAL SECURITY CLIENTS

(1) "Minnesota's Plan for the Care of the Medically Indigent"—Mr. Walter F. Finke, *Director, Minnesota Division of Social Welfare of the Department of Social Security, St. Paul, Minnesota*
Alfred W. Adson, *Chairman, Medical Advisory Committee to the Minnesota Division of Social Welfare, Rochester, Minnesota*
(2) Mr. Walter G. Stumbo, *formerly Attorney for State Department of Social Welfare, Topeka, Kansas*
(3) Chas. H. Phifer, M. D., *Chairman, Illinois State Medical Society Advisory Committee to State Department of Welfare, Old Age Assistance Division, Chicago, Illinois*

"The Annual Meetings From the Standpoint of the Exhibitor"—Mr. C. H. Wantz, *President, Medical Exhibitors' Association, Convention Manager, General Electric X-Ray Corporation, Chicago, Illinois*

In Memoriam

Vincent John Hawkins

Dr. V. J. Hawkins, for fifty-three years a practitioner in Saint Paul, until his retirement in January, 1938, died December 15, 1940, at the age of eighty-five.

Dr. Hawkins was born October 3, 1855, in Conneaut, Ashtabula County, Ohio. He was of Irish descent. At the age of ten, he moved with his parents to Austin, Minnesota, traveling by oxcart and steamboat. This was immediately following the Civil War. His father had served from 1861 to 1865 with the Union Army.

Dr. Hawkins attended the Austin primary public schools and the Blooming Prairie high school. His medical degree was obtained at Rush Medical College, Chicago. The medical training at that time consisted of a 2-year course, but Dr. Hawkins took an extra year, graduating February 22, 1881. His medical diploma carries fourteen signatures, evidently of all his teachers. He also received a "Rush Medical College Certificate in Private Diagnosis" given by Joseph P. Ross, A.M., M.D. as well as a certificate from the Central Free Dispensary of West Chicago for a special course in eye and ear diseases.

Dr. Hawkins first practiced with his uncle, Dr. J. Palmer Johnson, in Blooming Prairie, Minnesota, from where he moved to Saint Paul in 1885. His medical license bears the date February 6, 1884. During his first year in Saint Paul he served on the staff of the City and County Hospital now known as the Ancker Hospital.

Dr. Hawkins' offices were in the Thompson Block at Isobel and South Wabasha Streets for fifty-three years. The outside door to the reception room was never closed or locked day or night. During the early days much of his practice was in the country and many trips by horse and buggy were made over muddy roads to patients in West Saint Paul and as far as the German settlement of Rosemount. Always fond of fine horses he owned five most of the time in the early days. He had some of them trained to gallop in harness by the fireman at a fire station near his house, and even at one time had a gong on his buggy. When he started to drive automobiles in 1910 all this was relegated to the past.

Dr. Hawkins was a general practitioner and performed some surgery. He had about 2,400 successful births to his credit. One of the obstetric cases in which he took great pride was a cesarian section performed September 14, 1889 on a midget seventeen years of age, three feet five inches tall and weighing fifty-eight pounds. Much of his surgery was emergency in character, performed at night in farm houses by the light of a kerosene lamp held outside the window to avoid ether explosion.

Dr. Hawkins was a member of the Ramsey County Medical Society from May 29, 1889 until he became an affiliate in 1928. He was a member of the Saint Paul Board of Library Directors from 1900 until 1905. He was a candidate for the State Senate in 1910. He was one of the first members of the Shekinah Lodge of the Masonic Order and a Past Grand Master of that lodge. He was also a member of the Woodmen of the World and medical examiner of that order for many years. He was a life member of the Riverview Commercial Club and assisted materially in the establishment of the West Side General Hospital. He was an Episcopalian and for many years served on the vestry of the Church of the Ascension as Senior Warden.

Dr. Hawkins had no hobbies but took great pleasure in the practice of medicine and attended medical meetings regularly.

Hugh H. Slocumb

Dr. Hugh H. Slocumb was born in Winona, Minnesota, November 22, 1882. He attended schools at Winona and also Shattuck Military Academy at Faribault, Minnesota.

Dr. Slocumb received his M.D. from the College of Medicine, University of Illinois in 1905, and practiced medicine at Ironwood, Michigan, for several years before moving to Plainview, Minnesota, where he was associated in practice with his brother, Dr. Jess Slocumb.

About 1914 Dr. Slocumb moved to Belgrade, Minnesota, where he enjoyed a good practice until he volunteered his services in 1917 during the World War. He married Hedwig Sund of Belgrade, June 1, 1918, and left the following month for France. Upon his return in 1919 he continued practice in Belgrade until 1929. On account of poor health he moved to California in 1929 and remained there until 1935, when he returned and located at Avon, Minnesota. He remained at Avon until his death, January 7, 1941, which was the result of a stroke suffered three years previous.

Dr. Slocumb is survived by his wife, one son and one daughter.

"For my part I am still unconvinced that the family doctor is an anachronism. I still want somebody to save me from unsuitable or excessive specialist advice; I need someone to coördinate the findings of specialists and discount them if necessary; and above all I want someone who is willing to talk to me, at length, about my migraine, my little boy's delinquencies, my wife's recent strangeness, my baby's inoculation, and my daughter's desire to marry a man with asthma."—LANCET. Copied by the *New York State Jour. of Med.*, (Jan.) 1940.

* * *

Nothing is more important at the present time than to continue and to intensify the campaign against tuberculosis and against syphilis, and I hope that no one will permit his attention to be swayed from the objectives we have in mind, because the fight against these diseases is more important at a time of crisis as a measure of national defense than it is in normal times.—FRANK C. BOUDREAU, M.D.

OF GENERAL INTEREST

Dr. M. J. Anderson is president of the Rochester Figure Skating Club.

* * *

Dr. and Mrs. John R. Paine of Minneapolis spent the holidays at Dr. Paine's home in Dallas, Texas.

* * *

Dr. and Mrs. F. M. McCarten of Stillwater are the parents of a daughter, Mary Ann, born December 15.

* * *

Dr. R. J. Ripple has been elected chief of staff at the Rice Memorial Hospital in Willmar.

* * *

Dr. L. E. Sjostrom of Storden has been named coroner of Cottonwood County.

* * *

Dr. and Mrs. E. James Brady of Minneapolis are the parents of a son, Dennis James, born December 15, 1940.

* * *

Dr. A. Keller Doss, formerly a fellow in the Mayo Foundation at Rochester, is practicing in Fort Worth, Texas. He has offices in the Medical Arts Building.

* * *

At a recent meeting of the American Statistical Association in Chicago, Dr. Joseph Berkson of Rochester was elected a Fellow of the organization.

* * *

Dr. D. W. Pollard of Minneapolis, acting superintendent of General Hospital for the past two years, has been made permanent superintendent of the hospital.

* * *

Dr. W. P. Olson has returned to Gaylord from California to take charge of the practice of his son, Dr. William P. Gaylord, while the latter is engaged in examining National Guardsmen.

* * *

Dr. Stuart W. Harrington of Rochester will deliver the annual Mayo lecture at Northwestern University Medical School, February 10. His subject will be "Diaphragmatic Hernia."

* * *

Dr. Simon D. Brimhall, formerly an associate in experimental surgery and pathology at the Mayo Clinic in Rochester, passed away January 10. Since his retirement in 1922 he had lived in Covert, Michigan.

* * *

Dr. Robert B. Tudor of Saint Paul has become a member of the Adams Hospital staff in Hibbing. He is a graduate of the University of Minnesota Medical School.

* * *

Dr. and Mrs. James H. Haines of Stillwater are grandparents for the second time, a son having been born to their daughter, Mrs. Lloyd A. Nelson of Minneapolis, January 3.

Dr. and Mrs. R. D. Thielen of Saint Michael recently moved into their new home, which also houses Dr. Thielen's offices. The building is of English cottage architecture, with exterior of stucco and stone.

* * *

Dr. W. S. Broker of Wadena is temporarily in charge of the Otter Tail County Sanatorium during the year's absence of Dr. L. J. Webster of Battle Lake, who has been called to active duty in the United States Army.

* * *

Dr. Peter Ward, administrator of Miller Hospital in Saint Paul was reëlected secretary of the Minnesota Hospital Service Association at a recent meeting. James McNee of Duluth is the new president.

* * *

Dr. Albert Fritsche was elected president of the staff at the Union Hospital in New Ulm, January 8. Other officers named are Dr. F. H. Dubbe, vice president; and Dr. C. A. Saffert, secretary.

* * *

Dr. J. L. Bollman of Rochester attended the national convention of Sigma Xi and a meeting of the American Association for the Advancement of Science in Philadelphia last month.

* * *

Dr. Harry A. Palmer of Blackduck married Miss Hulda T. Nyland of Minneapolis, December 21, 1940, in Minneapolis. They are at home in Blackduck, where Dr. Palmer is practicing.

* * *

Carl Drake, son of Dr. and Mrs. Carl B. Drake of Saint Paul, was a member of the Yale hockey team which played against the University of Minnesota six during the holidays.

* * *

Dr. William A. O'Brien, director of postgraduate medical education at the University of Minnesota, addressed a Farm and Home Week session in Saint Paul, January 23.

* * *

Dr. Arthur C. Strachauer of Minneapolis recently returned from a two-weeks' hunting trip at King Ranch, Armstrong-Norias, Texas, where he bagged wild turkeys.

* * *

A grant of $5,000 has been received by the University of Minnesota from the Carnegie Corporation of New York for continued support of investigations of viruses in relation to cell growth, being conducted under the direction of Dr. Robert G. Green.

* * *

Dr. Harry Hall of Minneapolis, orthopedist, has gone to England to be associated with the American Hospital in Britain, of which Dr. Wallace H. Cole of Saint Paul recently became director.

Dr. Charles B. Craft, National Cancer Research Institute Fellow at the University of Minnesota, addressed a women's group in Detroit Lakes, January 24, as the representative of the Minnesota State Medical Association.

* * *

Dr. H. L. Williams was in Boston recently to address members of the New England Otolaryngological Society. He was also in Philadelphia to attend a meeting of the American Laryngological, Rhinological and Otological Society.

* * *

Staff physicians at the Immanuel Hospital in Mankato have elected Dr. William Black as chief of staff; Dr. John A. Butzer, vice president, and Dr. F. W. Franchere of Lake Crystal, secretary. The hospital has purchased a shock-proof, portable x-ray machine.

* * *

Dr. Henry E. Michelson, Dr. Elmer M. Rusten, and Dr. Carl W. Laymon of Minneapolis, and Dr. John F. Madden and Dr. Francis W. Lynch of Saint Paul attended the annual meeting of the Chicago Dermatological Society, January 15.

* * *

Dr. Ruth E. Boynton, director of the Student Health Service at the University of Minnesota, was reëlected president of the American Student Health Service Association at its twenty-first annual meeting in Ann Arbor, Michigan, December 27 and 28.

* * *

Dr. Karl W. Anderson has been named head of the medical department of the Northwestern National Life Insurance Company, Minneapolis, succeeding the late Dr. Henry W. Cook. His appointment was effective as of January 1, 1941.

* * *

Dr. and Mrs. G. W. Clifford of Alexandria have gone to New Orleans where Dr. Clifford will take a six-weeks' postgraduate course in internal medicine at Tulane University Medical School. Dr. O. Braun of Minneapolis is in charge of his practice during his absence.

* * *

Dr. Willard Akins of the More Hospital staff in Eveleth, is the new city health officer in that city. He was appointed to that office January 1 by Mayor Richard C. Floyd who announced a rotation system for this position. He succeeds Dr. W. S. King, who continues as school health officer.

* * *

Dr. William Rademaker of Saint Paul has become associated in practice with Dr. H. W. Arndt in Detroit Lakes. Dr. Rademaker, a graduate of the University of Minnesota Medical School, was formerly with the Minnesota Division of Social Welfare. He will also have an office at Ogema.

* * *

Dr. T. F. Hammermeister was elected president of the staff of the Loretto Hospital in New Ulm at the annual meeting last month. Dr. Albert Fritsche was named vice president and Dr. F. H. Dubbe, secretary.

Dr. H. E. Mortensbak of Hanska read a paper, "Diseases of the Esophagus."

To safeguard patients from influenza, hospitals in Minneapolis last month ordered restrictions on visitors.

At the General Hospital, only the seriously ill were allowed visitors. Similar limitations were in force at the University Hospitals, while private hospitals were barring visitors with coughs or colds.

* * *

Dr. H. H. Kessler of Newark, New Jersey, orthopedist, will be one of the guest speakers at the eighty-eighth annual meeting of the Minnesota State Medical Association, to be held in Saint Paul, May 26, 27 and 28.

Dr. Kessler's subject will be "Rating of Disability."

* * *

Dr. R. A. Beise is the new chief of staff at St. Joseph's Hospital in Brainerd, being named to that position at a recent meeting. He succeeds Dr. J. A. Thabes, Sr.

Other officers named are: Dr. C. E. Carlson, Aitkin, vice chief, and Dr. V. E. Quanstrom, Brainerd, secretary-treasurer.

* * *

Dr. M. S. Henderson of Rochester was in New Orleans last month to attend meetings of the American Academy of Orthopædic Surgeons and the Committee on Fractures and Traumas of the American College of Surgeons. He also participated in giving the examinations of the American Board of Orthopædic Surgery.

* * *

Dr. F. W. Bachnik of the Adams Hospital staff in Hibbing, has gone to Chicago to begin a two-year fellowship in obstetrics and gynecology awarded him by the University of Chicago. He will do his graduate work at Lying-In Hospital operated by the University.

Dr. Bachnik plans to return to Hibbing to practice after completion of his fellowship. His wife and infant son will join him in Chicago in the spring.

* * *

Special courses of instruction in orthopedic nursing are being offered during the winter and spring quarters by the University of Minnesota for a limited group of public health and institutional nurses. The work is being offered with the assistance of the National Infantile Paralysis Foundation, Inc., and in collaboration with the Minnesota Department of Social Welfare, Division of Crippled Children, and the Minneapolis Curative Workshop.

* * *

Dr. Harry Wilmer of Minneapolis, former graduate student at the University of Minnesota who is now interning at Gorgas Hospital, Panama Canal Zone, is winner of the original research prize of Phi Delta Epsilon, national medical fraternity.

Dr. Wilmer was selected for the award at the fraternity's annual convention in Pittsburgh. He worked last year at the university with Dr. Richard E. Scammon. The findings of their research are to be incorporated in a book, "Human Growth and Developmental Anatomy."

Dr. J. S. Lundy of Rochester addressed a recent meeting of the Chicago Society of Anesthetists, and a meeting of the Englewood branch of the Chicago Medical Society. He also attended a meeting of the University of Michigan section of the American Chemical Society in Ann Arbor.

Dr. Walter C. Alvarez of Rochester addressed the Calumet Branch of the Chicago Medical Society, December 20, on "Abdominal Pain."

* * *

Dr. Henry E. Michelson of Minneapolis, director of the Division of Dermatology at the University of Minnesota Medical School, will address two state medical meetings in May.

He has been invited to present a paper at the Nebraska State Medical Association meeting in Lincoln, May 5 to 8, and also at the 1941 annual session of the South Dakota State Medical Association in Mitchell, May 19 and 20. At the latter meeting, he will present a clinic in addition to his paper.

* * *

Funeral services were held at Amery, Wisconsin, January 20, for Dr. John Andrew Regner, eighty-five, one of the last two members of the first class to be graduated from the University of Minnesota Medical School in 1889. Burial was in Lake City, Minnesota. He had practised in Superior, Wisconsin, and in Minneapolis, Wheaton and Cannon Falls, Minnesota.

With the death of Dr. Regner, who retired in 1931, Dr. Charles E. Dutton of Minneapolis is the only surviving member of the class.

* * *

First to hold the Harold Rypins Research assistantship in pediatrics at the University of Minnesota Medical School is Dr. Luigi Luzzatti.

The assistantship was established in honor of the late Dr. Rypins, who was a member of the faculty of the University Medical School for a number of years before going to New York to become secretary of the state board of medical examiners. The assistantship was established by a committee of Twin City physicians, aided by a group of interested and generous persons.

* * *

Dr. Oskar Diethelm of the Payne Whitney Psychiatric Clinic, New York City, and professor of psychiatry at Cornell University Medical College, addressed several meetings in Minneapolis early in January.

He spoke before the Minnesota Mental Hygiene Society on the subject, "The Aging Person"; and before the Minnesota Society of Neurology and Psychiatry on the topic, "A Historic Review of Psychiatric Treatment." He also addressed juniors and seniors in the University of Minnesota Medical School.

* * *

Dr. Martin Aune of Minneapolis has been appointed state surgeon of the Minnesota defense force with the rank of lieutenant colonel, according to an announcement by Col. F. G. Stutz, executive officer of the defense force. Dr. Aune has been assigned to the state staff with headquarters in Saint Paul.

A World War veteran, Dr. Aune served thirty years in the Minnesota National Guard. He retired from the National Guard service two years ago with the rank of major.

* * *

Life and work of interns at the General Hospital in Minneapolis is the subject of an eight-page photographic feature in the January 20 issue of *Life* magazine.

The University of Minnesota Medical School, the article points out, was the first to require internship for an M.D. degree.

Material for the story was obtained last fall when Dorothy Jane Larson, *Life* reporter, and Alfred Eisenstaedt, photographer, came to Minneapolis on the assignment.

* * *

Dr. Dean S. Fleming, Minneapolis epidemiologist, is scheduled to leave soon for England where he will become a staff member of a "siege hospital" being set up for the study of communicable diseases under war-time conditions. The hospital is a joint project of the American Red Cross and Harvard University.

Dr. Fleming, who is taking postgraduate work at Harvard University, is a graduate of the University of Minnesota Medical School. He has been an epidemiologist on the Minnesota State Board of Health.

The hospital to be erected in southwestern England has been prefabricated in the United States. It will be a 126-bed unit, consisting of twenty-two buildings.

* * *

A regional assembly of the Women's Field Army was conducted in Rochester, February 6 and 7, with the State Divisions of Minnesota, Iowa, North Dakota, South Dakota and Wisconsin participating.

Dr. A. W. Adson of Rochester coöperated in planning the program.

Speakers at the assembly dinner held at the Kahler Hotel, February 6, included C. C. Little, managing director of the American Society for the Control of Cancer, Inc., whose subject was "National Defense and Cancer Control," and Dr. W. A. O'Brien of Minneapolis, a director of the national society, and president of the Minnesota Society for the Control of Cancer.

* * *

Guest faculty members for the course in Uterine Bleeding at the Center for Continuation Study on the University of Minnesota campus, February 3 to 5, included George W. Bartelmez, professor of anatomy at the University of Chicago; Dr. Ralph A. Reis, assistant professor of obstetrics and gynecology at the Northwestern University Medical School, Chicago, and Dr. Robert Meyer, formerly director of the pathologic institute of the first women's clinic in Berlin and now associated with the University of Minnesota Medical School.

The course was limited to those with special training in pathology, or obstetrics and gynecology.

* * *

Dr. A. H. Borgerson of Sebeka has purchased the practice of Dr. M. G. Ericsson in Long Prairie and his interest in the Long Prairie Hospital and Clinic. Dr. Borgerson began his association with Drs. M. E.

Mosby and B. L. Gifford in the hospital and clinic, January 1.

Dr. Ericsson has moved to Cedar Falls, Iowa, where he has purchased the practice of a physician who is retiring.

Dr. Borgerson, a graduate of Northwestern University Medical School in Chicago, practiced at Hewitt, Minnesota, before going to Sebeka where he has practiced eight years. During this period he has been a member of the Wesley Hospital staff in Wadena.

* * *

A new degree, Master of Public Health, is to be conferred by the University of Minnesota through the Medical School, as the result of action taken at a recent meeting of the board of regents.

The degree replaces a certificate in public health, which previously has been issued to those completing the work. Candidates for the new degree are required to have prior professional training and a prior professional degree—that is, be graduate physicians, dentists, veterinarians, or graduate nurses who already hold a bachelor degree in public health nursing.

The program of studies leading to the degree will contain not less than forty-five credit hours of professional work in preventive medicine and public health.

* * *

Among Naval Reserve medical officers called to active duty are:

Dr. T. B. Magath of the Mayo Clinic staff in Rochester, assigned to Caribbean area for limited service. He has been stationed in Guantanamo Bay, naval base in Cuba.

Dr. James B. Vail of Henning, lieutenant, assigned to Second Marine Brigade, Fleet Marine Force, Marine Corps Base, San Diego, California.

Dr. W. McK. Craig and Dr. Waltman Walters of Rochester, for limited service.

Dr. H. W. Sybilrud, Bricelyn, who will serve as Lieutenant Commander of the United States Naval Reserve Medical Corps in the Second Marine Brigade. He reported for duty at San Diego, February 4.

* * *

Eighty ophthalmologists and otolaryngologists attended the Course in Ophthalmology at the University of Minnesota Center for Continuation Study, January 20-25. Of the eighty, all except four limit their practice to this field, and half of this group are members of special societies certified by the American Board.

Guest instructors included Dr. Ramon Castroviejo, instructor in ophthalmology at the Columbia University College of Physicians and Surgeons in New York; Dr. Albert D. Ruedemann, head of ophthalmology at Cleveland Clinic in Cleveland, Ohio; Dr. Derrick T. Vail, Jr., professor of ophthalmology at the University of Cincinnati College of Medicine; and Dr. Robert Von Der Heydt, associate professor of ophthalmology at Rush Medical College at the University of Chicago.

* * *

Among guest members of the faculty for the Continuation Course in Hospital Administration conducted January 27-February 1 on the University of Minnesota campus were: Dr. Arthur C. Bachmeyer, director of University of Chicago Clinics; Nellie J. Gorgas, assistant to the director of University of Chicago Clinics; Dr. Malcolm T. MacEachern, associate director of American College of Surgeons; Joseph G. Norby, superintendent of Columbia Hospital in Milwaukee; C. Rufus Rorem, director, Commission on Hospital Service, American Hospital Association, Chicago; and Dr. Stanley J. Seeger, Chief of the Medical Staff of Columbia Hospital in Milwaukee.

A feature of the course was Trustee Day, January 31, when hospital trustees were guests.

* * *

A plaque was presented recently by the Minnesota Hospital Association to the Glenwood Community Hospital at Glenwood, winner of the contest for small hospitals held last May.

The presentation took place at a dinner in Glenwood at which hospitals in Benson, Clarkfield, Montevideo, Morris, Fergus Falls, Starbuck and Willmar as well as the Anoka State Hospital, were represented.

Ray Amberg of Minneapolis, association president, made the presentation. Dr. W. C. Rydburg, chief of staff of the hospital, described the staff organization.

Others who took part in the program included Dr. Walter Gardner, first vice president of the association, and Dr. A. F. Branton, executive secretary.

* * *

Several members of the University of Minnesota Medical Staff have completed motion pictures made by the Visual Education Service of the University of Minnesota.

A two reel, 16 mm. silent, colored film, entitled, "Hemorrhoidectomy; Dissection Method," was completed recently by Dr. Walter A. Fansler of Minneapolis. Pictures were taken by Clayton Wall.

Two movies have been made by Dr. Frank E. Burch of Minneapolis, both 16 mm. silent, colored. One is entitled, "Intracapsular Cataract Operation" and the other, "Extracapsular Cataract Extraction with Peripheral Iridectomy." Photographer for the latter was Lawrence Glesnes.

Robert A. Kissack, Jr., is director of the service and Paul Wendt, production manager.

* * *

The next examination for appointments as commissioned officers in the Medical Department of the Navy will be held at all of the larger naval hospitals and at the Naval Medical Center in Washington, D. C., May 12 to 15, inclusive, it is announced by Rear Admiral Ross T. McIntire, the Surgeon General of the Navy.

Applicants for appointment as Assistant Surgeon, effective about two months from date of examinations, must request authorization to appear for examination before April 21. Applicants must be between the ages of twenty-one and thirty-one years and graduates of Class "A" medical schools. They must have had at least one year of intern training in an accredited hospital.

Additional information may be obtained by addressing the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Physicians who received advanced degrees from the University of Minnesota Medical School at the end of the 1940 fall quarter included: Drs. Wallace A. Merritt, John S. Bagwell, Jr., Alice G. Hildebrand, Lamont R. Schweiger and Donald MacLean Willson, all of Rochester, Masters of Science in Medicine.

Dr. Robert W. Brown of Fort Steilacoom, Washington, Master of Science in Neurology and Psychiatry. Dr. Calvin M. Kershner, Rochester, Master of Science in Ophthalmology. Dr. Henry H. Young, Rochester, Master of Science in Orthopedic Surgery. Dr. George C. Kimmel, Rochester, Master of Science in Pediatrics. Dr. Christopher Robert Dix, Rochester, Master of Science in Plastic Surgery.

Drs. Ercel A. Addington of Spokane, Washington, and John A. L. McCullough, Leo Axel Nash and Everett E. Seedorf, Rochester, Masters of Science in Radiology.

Drs. Morris T. Friedell, William B. Condon, Robert C. Derbyshire, Russell M. Jensen, James M. Leffel, Jr., Karl Chandler Randall, II, Carl P. Schlicke, Wendell S. Sharpe, Francis M. Thigpen, Richard P. Waggoner and Donald H. Wrork of Rochester, and Rochfort W. Kearney of Mankato, Masters of Science in Surgery.

Dr. Samuel Nesbitt of Rochester, Doctor of Philosophy in Medicine. Dr. Charles F. Code, Rochester, Doctor of Philosophy in Physiology.

* * *

Medical Reserve officers called to active duty in the United States Army within the last month include:

Captain Arthur Francis Dworak of Saint Paul, to Fort Bliss, Texas.

Captain Eugene John McCann, Minneapolis, assigned to Fort Snelling.

Dr. Daniel H. Autry, first lieutenant, Rochester; Dr. Francis C. Usher, captain, Rochester; Dr. Alvin John Meyer, captain, Lake City, all assigned to Camp Joseph T. Robinson, Arkansas.

Captain Frank Tracy Cavanor of Minneapolis, Captain Arthur M. Mulligan of Brainerd; First Lieutenants Leo James Conlin of Saint Paul, Harold J. Frank of New Prague, Albert T. Hays of Minneapolis, Morris Cable of Minneapolis, Jerome Scanlan of Saint Paul, Leslie Closson of Minneapolis and Louis Odessky of Saint Paul, all assigned to Carlisle Barracks, Pennsylvania.

Dr. Kinsey MacLeod Simonton, first lieutenant, Rochester; Dr. Carleton Schleuder Strathern, first lieutenant, Saint Peter; Dr. Paul Edgar Swanson, first lieutenant, Virginia; Dr. Alfred Uihlein, first lieutenant, Rochester; and Dr. Louis D. Vaughn, first lieutenant, Rochester, all assigned to Camp Grant, Rockford, Illinois.

Col. William D. Borden, M.C., Fort Snelling, has been transferred to Camp Eustis, Virginia.

Dr. Frederick A. Smith, first lieutenant, Rochester, to Army Medical Center, Washington, D. C.

Boyer's Semi-centennial of Practice*

"To be seventy years young is sometimes far more cheerful and hopeful than to be forty years old."—

Oliver Wendell Holmes on the seventieth birthday of Julia Ward Howe, 1889.

It is not often in our community a physician practices his profession fifty years. Right now we have such a physician—Dr. Samuel Boyer. It is our pleasure, as his professional confrères, to do him honor at this item for his example in devotion to practice, his studiousness, tolerance and understanding. We are proud of a fellow practitioner who can reach his age and carry with him a well digested conception of new discoveries together with the sensible method of applying them. His analytical mind and his understanding of men's motives have helped make him successful in medicine and in politics. It was once said he poised the policies of a certain political party in the palm of his hand.

Doctor Boyer always conducts himself like a gentleman. He is motivated by a kindly spirit which pervades any conversation with him. His kindly smile and an occasional chuckle are in evidence of his keen sense of humor. A joke on himself is as good to him as a joke on others.

Love of the great outdoors has been and still is his pet diversion. In the early days he took long hikes in the woods, sometimes of several days' duration, and the wilderness was a real wilderness then, but he knew how to make himself at home there. The winters were severe and settlements were few and far between. Wild animals were plentiful and fishing was supreme. In town he always prided himself on having the finest of driving horses.

His quiet dignity and his deliberate manner together with his thoroughness and wise judgment give force to the position he may take on any issue. Usually he is very "firmly of the opinion," one way or the other.

His kinship with his son is exemplary and with that in generous measure for all younger men coming up in the profession. He believes in passing on to them as much as possible of the richness of experience of his own generation.

Today, the youngest older man in our beloved profession in Duluth is the man to whom we extend this recognition, Dr. Samuel Huntington Boyer, Sr.

---

*The above tribute was read at the annual meeting of the staff of Saint Luke's Hospital, Duluth, Minnesota, held January 16, 1941.

At the same time a letter from the Board of Governors of the hospital was read indicating intention of the Board to place a bronze tablet in the hospital dedicated to Dr. Samuel H. Boyer on which will be inscribed all the names of the chiefs of staff of the hospital.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR FEBRUARY

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis; Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Professor of Preventive Medicine and Public Health, Medical School, University of Minnesota.

The program for the month will be as follows:

February 1—Posture and Backache

February 8—Causes of Backache

February 15—Back Injury

February 22—Periodontia

AMERICAN COLLEGE OF SURGEONS TO HOLD SECTIONAL MEETING IN MINNEAPOLIS

March 10, 11 and 12 have been set as the dates for a Sectional Meeting of the American College of Surgeons in which the states of Minnesota, North and South Dakota, Iowa, Nebraska, Montana, Kansas and Wisconsin, and the province of Manitoba will participate. Headquarters will be at the Nicollet Hotel, in Minneapolis.

The sixteen approved hospitals of Minneapolis will provide an excellent clinical background for the College meeting. Many of them will hold operative and non-operative clinics each morning during the meeting, and will also hold demonstrations of hospital procedures for the hospital executives who will attend the Hospital Conference which will also be sponsored by the College during the same three days.

Distinguished surgeons from all parts of the country will address the scientific sessions and lead the conferences and panel discussions. Among them will be the president of the College, Dr. Evarts A. Graham, professor of surgery at Washington University Medical School, St. Louis. At the headquarters hotel there will be educational and scientific exhibits and showing of motion pictures portraying surgical and hospital procedures. A large public meeting on the subject of "Conservation of Health" on the evening of the third day will be the final feature.

The Committee on Local Arrangements consists of Dr. W. A. Hanson, Chairman; Dr. William E. Patterson, Vice Chairman; Dr. Myron O. Henry, Vice Chairman; and Dr. James M. Hayes, Secretary. The chairman of the sub-committee on clinics is Dr. L. Haynes Fowler; on exhibits, Dr. Frederick A. M. Olson; on the Meeting on Health Conservation, Dr. Thomas J. Kinsella; on program, Dr. James A. Johnson; on public relations and speaking assignments, Dr. Martin Nordland; on reception and entertainment, Dr. Theodore H. Sweetser; on speaking equipment and motion pictures, Dr. Arthur F. Bratrud; on transportation and hotels, Dr. H. E. Hoffert; and on ladies' entertainment, Mrs. James A. Johnson.

The medical profession at large, as well as hospital trustees, superintendents, pathologists, dietitians, and other hospital executive personnel, are invited to attend the sessions of the Sectional Meeting and the Hospital Conference, a sufficiently varied program having been arranged to interest members of the several professions which are concerned with service to the sick and injured.

Among the speakers at the evening sessions and the leaders and collaborators in panel discussions will be Dr. Frank E. Adair and Dr. John Scudder of New York City; Dr. I. Mims Gage of New Orleans; Dr. Edwin C. Hamblen of Durham, North Carolina; Dr. C. C. Higgins of Cleveland; Dr. Howard K. Gray of Rochester, Minnesota; Dr. David Cleveland and Dr. Roland S. Cron of Milwaukee; and Dr. Paul B. Magnuson, Dr. Warren H. Cole, Dr. C. B. Puestow, Dr. Michael L. Mason, Dr. Marshall Davison, and Dr. R. W. McNealy of Chicago.

Some of the subjects for panel discussions which have already been selected are, "Evaluation of Disability Following Fractures"; "Blood Transfusion"; "Carcinoma of the Colon and Rectum"; "Chemotherapy in Surgical Infections"; "Choice of Operation for Relief of Vesical Neck Obstruction"; "Complications in Surgery of the Biliary Tract"; "Craniocerebral Injuries"; "Endocrinology in Gynecology"; "Gastric Surgery for Non-cancerous Lesions"; "Hand Injuries"; "Indication for Cesarean Section"; "Proper Choice of Anesthetics with Indications and Contra-Indications"; "Thoracic Surgery"; "Thyroid Surgery"; "Treatment of Hernia by Surgery and by Injection"; "Use of Chemotherapy Before and After Urologic Surgery"; "Varicose Veins"; and "Cancer."

The clinical program will also include a wide range of subjects. Of especial interest will be the cancer clinic and the fracture clinic, and a presentation by the younger surgeons at one of the hospitals of surgical research that is in progress.

Minnesota State Executive Committee,
Waltman Walters, M.D., Rochester
Secretary: James M. Hayes, M.D., Minneapolis
Counselors: William A. Coventry, M.D., Duluth
Harry P. Ritchie, M.D., Saint Paul
Owen H. Wangensteen, M.D., Minneapolis

DR. WHITE TO TALK AT UNIVERSITY

Dr. Paul D. White of the Massachusetts General Hospital, Boston, and the Harvard Medical School, will speak at the University of Minnesota Medical Science Amphitheater, February 28, at 8:15 p. m. His subject will be "Enlargement of the Heart."

Dr. White is also scheduled to give an address at Rochester, February 27.

MINNESOTA PATHOLOGICAL SOCIETY

When the Minnesota Pathological Society meets February 18, Dr. Frank C. Andrus will present a paper, "Gout Nephritis," and Dr. Henry E. Michelson, a paper, "Beck's Sarcoid."

VITAMIN K DISCOVERER TO SPEAK AT UNIVERSITY

Dr. Henrik Dam, associate professor of biochemistry at the University of Copenhagen and discoverer of vitamin K will lecture at the University of Minnesota under the auspices of the Medical School, February 24, at 8 p. m. in Room 15 of the Medical Science Building. His subject will be "Vitamin K—Biochemistry and Clinical Applications."

Dr. Dam will speak at Rochester, February 20.

GEORGE CHASE CHRISTIAN LECTURE

"Present Knowledge of Carcinogenesis," was the title of the lecture presented by Dr. F. Peyton Rous of the Rockefeller Institute for Medical Research, as the tenth annual George Chase Christian Lecture, February 5, at the University of Minnesota Medical School.

At a luncheon round-table on the day of the lecture, Dr. Rous discussed "Latent Neoplastic Changes and Conditional Tumors."

UNIVERSITY OF MINNESOTA INTERDEPARTMENTAL SEMINAR

The program for the Interdepartmental Seminar at the University of Minnesota Medical School to be presented Wednesday, February 26, at 8:00 p.m. in Eustis Amphitheatre, follows:

"The Kinetics of Gas Movement in Respiration with Particular Reference to Helium."—Drs. Robert B. Dean and M. B. Visscher.

"An Analysis of Twenty-seven Cases of Patent Ductus Arteriosus with Physiological Studies"—Dr. Ancel Keys, Laboratory of Physiological Hygiene, and Dr. M. J. Shapiro, Lymanhurst Clinic of the City of Minneapolis.

CLINICAL CONFERENCE OF MID-WESTERN RADIOLOGISTS

The fifth annual clinical conference of Mid-Western Radiologists will be conducted at Rochester, February 14 and 15. Following precedent established by previous conferences, members of the clinical, surgical and laboratory staffs of the Mayo Clinic will present the program. Scientific session will be conducted in Plummer Hall in the Mayo Clinic building.

Official headquarters will be the Kahler Hotel, where an informal banquet will be held Friday evening, February 14.

Dr. B. R. Kirklin of Rochester is local chairman of arrangements.

A special train will be operated between Chicago and Rochester for the conference.

VAN METER PRIZE AWARD

The American Association for the Study of Goiter again offers the Van Meter Prize Award of $300 and two honorable mentions for the best essay submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the Association which will be held at Boston, Massachusetts, May 26, 27, and 28, providing essays of sufficient merit are presented in competition.

The competing essays may cover either clinical or research investigations; should not exceed three thousand words in length; must be presented in English; and a typewritten double spaced copy sent to the Corresponding Secretary, Dr. W. Blair Mosser, 133 Biddle Street, Kane, Pennsylvania, not later than April 1.

The committee, who will review the manuscripts, is composed of men well qualified to judge the merits of the competing essays. Dr. Brien T. King of Seattle, Washington, received the Award for the year 1940 in recognition of his essay entitled "A New and Function-restoring Operation for Bilateral Abductor Cord Paralysis."

A place will be reserved on the program of the annual meeting for presentation of the Prize Award Essay by the author if it is possible for him to attend. The essay will be published in the annual Proceedings of the Association. This will not prevent its further publication, however, in any journal selected by the author.

BLUE EARTH COUNTY MEDICAL SOCIETY

The Blue Earth County Medical Society, in coöperation with the Blue Earth County Public Health Association, carried on an immunization campaign during the fall months of 1940.

During this period, 2,298 smallpox vaccinations and 1,999 diphtheria immunizations were administered. Rural Blue Earth County, as well as Mankato, was completely covered during the campaign, and an effort was made to give every child in the county the opportunity of this protection.

The Society intends to carry on a Mantoux testing campaign during the early months of 1941.

ST. LOUIS COUNTY MEDICAL SOCIETY

Dr. G. C. MacRae of Duluth was named president-elect of the Saint Louis County Medical Society at the organization's annual meeting last month. He will take office next year.

Dr. A. O. Swenson of Duluth, chosen president-elect last year, assumed the office of president held during the past year by Dr. T. L. Chapman.

Dr. S. H. Boyer, a practicing physician in Duluth for almost fifty years, was honored guest at the meeting.

Other officers named are: Dr. Clarence Jacobson of Chisholm, vice president; Dr. R. P. Buckley, Duluth, secretary-treasurer.

New delegates to the state medical meeting are Drs.

A. N. Collins and L. A. Barney of Duluth. Alternate delegates are Drs. M. H. Tibbetts and Mario Fischer, Duluth.

Delegates elected last year, who will continue to serve are: Drs. G. T. Ayres of Ely, H. E. Binet of Grand Rapids and J. R. Manley of Duluth. Alternate delegates are: Drs. P. G. Boman, C. M. Smith and P. S. Rudie, Duluth.

New committeemen are: Drs. P. G. Bowman and J. R. McNutt, Duluth, and Dr. A. Sinamark, Hibbing, economics; Dr. F. J. Hirschboeck, Duluth, advisory; Drs. Sinamark, W. E. Hatch and W. N. Graves, Duluth, judiciary.

Other committeemen, whose appointments hold over, are: Drs. C. O. Kohlbry and R. J. Moe, Duluth, advisory; Drs. J. K. Kuth, D. L. Tilderquist, E. L. Tuohy and R. S. Forbes of Duluth, O. W. Parker of Ely and Dr. Jacobson, judiciary; Drs. W. D. Coventry, C. H. Schroder, A. G. Athens of Duluth, Dr. Ayres and Dr. R. B. Bray, Biwabik, economics.

GOODHUE COUNTY MEDICAL SOCIETY

Dr. W. W. Liffrig of Goodhue is the newly elected president of the Goodhue County Medical Society. Other officers, chosen at a meeting last month in Red Wing, are: Dr. R. B. Graves of Red Wing, vice president; Dr. J. F. Brusegard, Red Wing, secretary-treasurer.

Dr. R. F. Hedin of Red Wing was chosen delegate to the state meeting of the Minnesota State Medical Association, and Dr. M. W. Smith was named alternate.

WASHINGTON COUNTY MEDICAL SOCIETY

Dr. Alexander McEwan of the staff of the Northern Pacific Hospital in St. Paul was guest speaker at the meeting of the Washington County Medical Society in Stillwater, January 14. He presented a paper on "Arthritis," discussing classification, etiology and treatment.

WOMAN'S AUXILIARY

Mrs. M. A. Nicholson, Duluth, Minnesota, *President*
Mrs. E. V. Goltz, 2259 Summit Avenue,
Saint Paul, *Publicity Chairman*

Mrs. M. E. Nicholson of Duluth, Minnesota, president of the Auxiliary to the Minnesota State Medical Association, and Mrs. John J. Ryan, president-elect, and historian on the Board of the Auxiliary to the American Medical Association, attended the Board Meeting of the Auxiliary at the Palmer House in Chicago, Illinois, November 29, 1940.

Board members who arrived on Thursday were taken on a tour of the offices of the American Medical Association at 535 North Dearborn Street. This was of great interest to the many women attending.

The Board meeting was called to order at 9 A. M. and was in continuous session until six o'clock. At noon a luncheon was served and Mrs. V. E. Holcombe, national president, introduced the members of the Advisory Council of the Medical Society, Drs. Arthur W. Booth, chairman, James R. Bloss, Ralph A. Fenton, R. L. Sensenich. (Drs. West and William F. Braasch are the other members of the Council but were unable to attend the luncheon.) Dr. Booth read a report of the Advisory Council with their recommendations for the future actions of the Auxiliary. Dr. Nathan Van Etten, president of the American Medical Association, gave a talk that was both humorous and inspiring. Mrs. Holcombe introduced Mrs. Samuel Clark Red, organizer and first president of the Woman's Auxiliary, who gave a very inspiring talk on the growth and possibilities of the Auxiliary. She complimented the states on their great interest and urged them to continue to be a true auxiliary.

Mrs. H. E. Christenberry, circulation manager of the *Bulletin,* reported a mailing list of 1,276. The state reports were given, Mrs. M. E. Nicholson reporting for Minnesota. The Nominating Committee was elected, with Mrs. Ryan as elections chairman. Plans were discussed for the convention of the Auxiliary in Cleveland, Ohio, in June. Mrs. James Blake was president of the national Auxiliary when it met in Cleveland in 1934 and at that time there was no state Auxiliary. Ohio is the latest state to join Auxiliary ranks and Mrs. J. Edwin Purdy the Ohio president was introduced and reported tentative plans for the convention. Mrs. Ryan, as chairman of the special History Committee, recommended that the History, which is being compiled, be printed in 1942 when the Auxiliary will have been in existence twenty years and that the minutes and reports be bound every five years to serve as a future History of the organization. Mrs. M. E. Nicholson will report further matters of interest at the next Board meeting of the State Auxiliary.

Olmsted-Houston-Fillmore-Dodge Counties

The Olmsted-Houston-Fillmore-Dodge Auxiliary held a meeting January 8 in Rochester and Dr. F. M. Feldman, director of District 3, Minnesota Department of Public Health and deputy health officer of Rochester, spoke on the undesirable housing conditions of Rochester. Mrs. T. B. Magath, president, appointed the following chairmen for the entertainment next month when the regional meeting of the Women's Field Army to the Society for the Control of Cancer is held. The committee appointed includes Mrs. B. T. Horton, Mrs. C. W. Rucker, Mrs. L. P. Howell and Mrs. P. S. Hench. The public relations chairman, Mrs. Horton, also spoke at the meeting.

St. Louis County

St. Louis County Auxiliary held its monthly meeting January 14 at the home of the president, Mrs. W. N. Graves, Duluth. After the business meeting the members did Red Cross work. The big project for the St. Louis County Auxiliary this year is the furnishing of the patients' sitting room at the Nopeming Sanatorium.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of November 13, 1940

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 13, 1940. Dinner was served at 7 o'clock and the meeting was called to order at 8 p.m. by the president, Dr. James Johnson.

There were thirty members present.

Minutes of the October meeting were read and approved as read.

The Secretary read a letter from Dr. L. C. Bacon, of Saint Paul, asking that his name be put on the Senior membership list. A motion was carried that this be accepted.

Dr. William F. Braasch read a memorial to Dr. C. B. Wright, and a motion was carried that it be accepted and spread on the minutes, and a copy sent to the family.

CHARLES BENJAMIN WRIGHT

1876-1940

The members of the Minnesota Academy of Medicine are largely familiar with the wide range of medical endeavor in which our late beloved colleague, Dr. C. B. Wright, participated. They also know of the long list of official positions which he so ably filled. There is no object in enumerating them again. However, these activities alone did not set him apart. It is his other qualities of mind and spirit which made him a physician of unusual attainments, outstanding in his contributions to the economic and scientific progress of American Medicine, and a citizen of exceptional value to society. It is true that he was classified in the medical registry as an internist, since he was a Fellow of the American College of Physicians and a Diplomat of the American Board of Internal Medicine, yet he was interested and well informed in many other phases of medicine. He took a personal interest in the medical and allied problems of many patients who had consulted him over a long period of years and he advised and directed their welfare much like the general practitioner of old. In many respects he represented the ideal practitioner of modern American Medicine.

His interest in the economic and general problems affecting the practice of medicine began with his participation in the affairs of the Hennepin County Medical Society. His intelligent approach to their problems and their solution was appreciated by his colleagues, who gave him official recognition and sought his counsel. His unusual intelligence in this field was recognized by Dr. Herman Johnson, who was not slow to draft him into the service of the Minnesota State Medical Association. A fine friendship arose between these two outstanding men which ended only with the untimely death of Dr. Johnson. Working together they were instrumental in developing medical reforms and in laying plans for the future which gave the Minnesota State Medical Association a predominant position in the legislative affairs of our state and which received national recognition as well.

Valuable as were his services to the State Medical Association, his influence in the solution of national problems involving medicine was even greater. His intelligent appraisal of the various problems confronting American Medicine and his peculiar genius for the solution of such problems soon became apparent to the members of the House of Delegates of the American Medical Association and they elected him to membership on the Board of Trustees. He was not long a member of this powerful body before he was made chairman of its Executive Committee, probably the most responsible position in the entire organization of the American Medical Association. There was no one in the land who had a clearer understanding of the many difficult problems which confronted the medical profession. His keen mind would quickly discern the crux of a problem and any solution which he volunteered was invariably sound and logical. It was generally recognized that he accepted these responsibilities in a most efficient manner. In fact, he devoted so much of his time and effort to the problems of organized medicine that he sacrificed his personal interests. Would that his devotion to the cause of medicine might act as an example to many who gain but do not give.

Those of us who enjoyed his friendship profited greatly. To be in his company was a privilege. His keen analysis of things, his kindly humor, his love of truth and of law and order, were a constant source of inspiration. He will long be remembered as a wise counselor in medical affairs in county, state and nation, as a representative of the ideal in the practice of medicine and for his unselfish endeavors in behalf of his fellow practitioners.

BE IT RESOLVED that a copy of this expression of our love and appreciation be sent to the members of his family with our deep sympathy.

W. F. Braasch

W. H. Condit

Dr. E. M. Hammes read a memorial to Dr. Arthur S. Hamilton, and a motion was carried that it be accepted and spread on the minutes, and a copy sent to the family.

ARTHUR STEPHEN HAMILTON

1872-1940

Dr. Arthur Stephen Hamilton died at his home in Minneapolis on June 2, 1940. He had been severely incapacitated for nearly five years from the residuals of a series of cerebral vascular accidents.

Doctor Hamilton was born at Wyoming, Iowa, November 28, 1872. He graduated from the University of Iowa and then transferred to the University of Penn-

sylvania for his medical training, receiving the M.D. degree from that institution in 1897. His course through the Medical School represented a period of considerable hardship due to financial stringency which imposed a limited diet upon him and necessitated extracurricular work to supplement his meager funds. The stimulation which he received as a student of Mills and Spiller was undoubtedly a potent factor in the choice of neurology and psychiatry as his specialty.

After receiving his medical degree, Hamilton became an assistant physician at the Independence State Hospital in Iowa and held that position until 1904. At Independence he became greatly interested in neuropathology and published numerous papers on the pathology of conditions which at that time had received very little attention from microscopists. At Independence he was associated with two other physicians who also were destined to advance our knowledge of neurology and psychiatry, Dr. Albert H. Barrott and Dr. Adolf Meyer. While at Independence he married Dr. Susanna P. Boyle, who was also a member of the State Hospital staff; there are no children of their union.

In 1904 Dr. Hamilton moved to Minneapolis, Minnesota, entering the practice of neurology and psychiatry, receiving an appointment as instructor in neuropathology at the University of Minnesota. He advanced through the academic ranks to a full professorship which he received in 1916. In 1912 he was made Director of the Division of Nervous and Mental Diseases and was Professor and Director until the onset of his terminal illness in 1935. Two extended study trips abroad gave him familiarity with clinical methods of Germany and England, especially the latter; these he applied in his practice and emphasized in his teaching.

Doctor Hamilton was elected to membership in the Minnesota Academy of Medicine and read his inaugural thesis on January 5, 1910, entitled "Paretic Conditions in the Aged." He served as its president from September, 1923, to September, 1924, and his presidential address was entitled, "Historical Survey of the Minnesota Academy of Medicine."

Doctor Hamilton served in 1918 and 1919 as Captain and Major in the U. S. Army during the World War.

Doctor Hamilton was considered by his students to be an unusually systematic and lucid teacher both in the lecture room and at the bedside. His breadth of knowledge, clear analytical thinking, careful technic, gentleness with patients and consideration for the younger colleagues' opinion constituted in him the nearly ideal combination for an advisor and preceptor of the more advanced students.

Though rather reserved and dignified, he was never austere or supercilious, but was approachable, friendly, and rarely ruffled. His appreciation of the social implications of neurology and psychiatry drew him into active participation in civic affairs so that he was frequently consulted on matters involving the welfare of the community and the state. Preferring the pursuits of practice, teaching and investigation he nevertheless was an active participant in numerous national and local societies; he was a past president of the Central Neuropsychiatric Association and former chairman of the Section on Nervous and Mental Diseases of the American Medical Association.

Minnesota and its environs have benefited from the presence of Arthur Hamilton. His many friends grieve over his passing.

J. C. McKinley, M.D.
E. M. Hammes, M.D.

Upon ballot, the following men were elected as candidates to Active membership in the Academy:

Max W. Alberts.....Saint Paul
Erling W. Hansen.....Minneapolis
Donald McCarthy.....Minneapolis
Archie H. Cardle.....Minneapolis
William Sadler.....Minneapolis

The scientific program followed.

HYPERTENSION AND SURGICAL DISEASE OF THE KIDNEY

William F. Braasch, M.D.
Rochester, Minnesota

Dr. Braasch read a paper on the above subject and showed several lantern slides.

Discussion

Dr. Arnold Schwyzer, Saint Paul: We surely want to thank Dr. Braasch for bringing this subject before our Society. It is a very valuable paper especially for the surgeon, inasmuch as, even in the presence of considerable hypertension, we can go ahead and operate with more assurance and an easier mind if an operation on the kidney appears imperative. Such a study, to be impressive and of real value, must be done on a very large amount of material which, of course, Dr. Braasch had at his command.

Dr. H. B. Zimmermann, Saint Paul: It would be interesting if Dr. Braasch would compare the statistics in this paper with another series of major surgical procedures done on individuals with high blood pressure but with no thought of reducing the blood pressure. I have seen a great many cases, for instance, of women with hypertension who were relieved for long periods of time following a hysterectomy for fibroid tumors.

About two years ago I did a major amputation on a man in his early forties for a peripheral vascular disease. He had a severe hypertention. Since his amputation, his pressure rarely goes over 140.

One of the best results I have ever had from a supradiaphragmatic splanchnic resection was in an individual where I had to abandon the operation before I had finished.

There is something mysterious about hypertension, and I am personally convinced that a major surgical procedure often does something to change these patients' mode of life in such a way as to favorably influence the hypertension.

Dr. John F. Noble, Saint Paul: We have had some opportunity to watch the response of hypertension to the removal of a diseased kidney and our clinical impression has hardly been favorable. One case in particular comes to mind. The patient was a girl in her teens who was suffering from severe hypertension which was at first thought to be essential in nature. After urologic examination, it was decided that the pyelogram on one side suggested a picture of pyelonephritis with contraction of the kidney. This was somewhat supported by the clinical history. In spite

of the fact that the preponderance of the clinical opinion favored the diagnosis of essential hypertension, the small kidney was removed. The histologic picture was that of an arteriosclerosis of the kidney with some evidence of a chronic pyelonephritis. There was a distinct reduction of blood pressure after the nephrectomy for a period of six to eight months, with corresponding clinical improvement. The hypertension recurred, however, and the patient went on to death in a period of less than two years due to a renal insufficiency on an arteriolosclerotic basis. I believe the temporary decrease in blood pressure was simply secondary to the surgical operation.

Long periods of freedom from hypertension have been reported, as pointed out by Dr. Zimmermann, to follow major surgical procedures entirely unrelated to the kidney. Our experience has been very limited, but we have been frankly skeptical of many of the reported cures of hypertension following nephrectomy. One cannot question the brilliance and importance of Goldblatt's work, but it is questionable whether his experimental material can be directly applied to the problem of human essential hypertension.

TUMORS SIMULATING CARCINOMA—HAND-SCHÜLLER-CHRISTIAN'S DISEASE

William A. Hanson, M.D.

Minneapolis, Minnesota

These tumors which have been reported increasingly since they were first reported by Rayer in 1836, Hand in 1893, Schüller in 1916 and Christian in 1919 are of interest in all fields of medicine and dentistry. So intimately is this clinical entity related to xanthomatosis and the reticulo-endothelial system that a sharp line of demarcation cannot be established, and therefore these two will necessarily be included in the discussion. The importance of the reticulo-endothelial system may be ascertained in a textbook of hematology.

Hand-Schüller-Christian's disease is undoubtedly due to a disturbance of the cholesterol metabolism,[7] which view, however, is not completely accepted by the morbid anatomists who emphasize the primary inflammatory nature of the disease.[3] Some investigators believe a filterable virus may be a factor.[1]

Probably the greatest contribution and understanding of the disease was brought forth by Rowland in 1928.[7] He concluded that these tumors infiltrate the reticulo-endothelial system resulting from an infiltration of lipoids in excess in the body fluids and are an expression of the body's attempt to rid the body fluids of lipoids which cannot be properly excreted and therefore act as an irritant. The various lipoids, cholesterol, fatty acid esters, phosphatid lipoids, probably lipoid proteins, are concerned with the process, but the anisotropic esters of cholesterol have been most often observed and studied.[7]

Henschen[6] recognized seven clinical groups.

1. Cases with skeletal transformations, exophthalmos and diabetes insipidus (complete triad).
2. Cases with skeletal transformations and exophthalmos but without diabetes insipidus (incomplete triad A).
3. Cases with skeletal transformations and diabetes insipidus but without exophthalmos (incomplete triad B).
4. Cases with skeletal transformations but without exophthalmos and diabetes insipidus.
5. Cases with diabetes insipidus but without skeletal transformations.
6. Cases with disturbances of growth.
7. Cases of so-called xantho-sarcomatosis without skeletal transformations and without diabetes insipidus.

Etiology.—Probably hypercholesterinemia is the most fundamental cause of these xanthomatous lesions; however, such factors as trauma, inflammation and infection cannot be disregarded.[7]

The majority of the cases have been observed in children and relatively few after puberty or in middle or advanced age. The male sex is more often affected than the female. There is no race predilection or familial occurrence. It usually occurs as nodular discrete lesions in the slowly evolving adult forms and as a more diffuse process in the rapidly developing infantile cases. Apparently diet is not much of a factor although it may influence the condition in some cases where it has already manifested itself.

Pathology.—Hand-Schüller-Christian's disease may be regarded as a chronic disease. In this disease the lipoid containing lesions have a predilection for the dense connective tissue adjacent to the bones, especially the skull, and by pressure cause defects in the bones with sharp edges. They develop from the dura mater, periosteum and endosteum, filling the defects of the bone which they produce. They may also originate from the articular ligaments and protrude into the joint space.[3] They may be found in many different organs and tissues such as skin, mucous membrane, gums, palate, ribs, liver, spleen, spine, bones, tendons, peritendons, periarticular surfaces, etc. The spleen and liver may or may not be enlarged, and if enlarged they never reach the size which is observed in Gaucher's and Niemann-Pick's disease.[3] In the former in the parenchyma of the liver and spleen there are either no specific lesions or only small ones without diffuse general involvement.

The accumulation of cells filled with cholesterol esters has been observed also in many organs and structures and may be very minute or macroscopic in character.

The outstanding clinical features, diabetes insipidus and the exophthalmos, are the results of changes in the skull. In the cases with pulmonary fibrosis there may be respiratory difficulties with cyanosis and hypertrophy of the right heart.[3]

The lesions are variable in size and form with an abundance of protoplasm and dark staining nuclei, while in the fresh state the cells are sometimes loaded with fat droplets.[1] If the fat is dissolved out, the protoplasm becomes a fine areolar network with foamy or vacuolated appearance, therefore the foam cell. Due to the presence of giant cells, fibrocytes, eosinophilic leukocytes and round cells they have been considered inflammatory granulomas. These granulomas which

involve the bone may reach considerable size and be mistaken for a tumor. In contrast to real neoplasms, they do not correspond with hematogenous metastasis in their distribution and their lack of infiltrative and destructive character by avoiding vital tissues.[7] Also the xanthomatous nodule does not increase by multiplication of its cell element but by the addition of new cells. If considered from their relationship to the reticulo-endothelial system, they may be summed up from the following phenomena.[7] The constant presence of excess lipoid in the blood stream causes an irritation of the vessel walls; thus a perivascular infiltration takes place. At first, small round lymphocytes with little protoplasm appear; then by splitting of the vessel walls, a fusiform cell with an abundance of protoplasm develops, and owing to a fusion multinuclear xanthoma cells are formed. These cells all contain lipoid with a greater amount in the more mature cells. These cells may vary in size and form, but their nuclear structure is similar. They never show karyokinesis. The young cells are always in the center of the lesion near the blood vessel, and the older and more mature cells are at the periphery. The characteristic cells are not always observable in the lesions, and they may retrogress or recur after excision (Rowland). The lesions tend toward fibrotic involution, and in the process there is a resulting arrangement of wavy bands and whorls.[3] In the bones the defects are filled by dense connective tissue in which bone is formed by metaplasia, and the continuity of the bone may be restored.[3] Some cases resemble cystic osteofibrosis (Chiari). The lungs in some cases show fibrotic induration with a honey-combed appearance. Viet reports a case with a diffuse sclerosis of the glands of internal secretion. The xanthomatas may also undergo necrosis and calcification. Therefore with this varied pathology considerable difficulty may be encountered in making the diagnosis.

Symptoms.—The onset of the disease is insidious and periodic; it is usually far advanced before a physician is consulted. In children there has been a history of measles, scarlet fever, etc. Trauma probably plays a part. One of the earliest findings in children is an ulcerative gingivitis with loosening of the teeth, due to the destruction of the alveolar process of the jaw by the xanthomatous tissue.[7] The symptoms depend on the location of the disease, the extent of the lesions and the mechanical effects resulting from the pressure and bone destruction. Subjective symptoms may be slight, or there may be irritability, often tenderness and pain referred to the lesions which may be severe in the rapidly progressive cases.[3] Polyuria and polydipsia and protrusion of one or both eyes are the most outstanding symptoms.

The head may be deformed by soft subcutaneous swellings, or the defects may be felt in the skull. There may be deafness due to middle ear involvement. The triad of symptoms, defects of membranous bones, exophthalmos and diabetes, are due to xanthoma-like lesions in the skull. The lesions of the dura mater and the periosteum erode the bone and produce the defects. They affect the hypophysis, infundibulum and base of the brain and therefore lead to diabetes insipidus. They break into the orbits and produce a protrusion of the eyeballs. The exophthalmos may be extreme with or without optic nerve injury or choked disc. About 85 per cent of the cases have exophthalmos and diabetes insipidus. Arrest in growth is associated with diabetes insipidus, and in children anemia and cachexia are noted. In some cases there may be an unexplained fever. The skin may be a light yellow or brownish color. The lesions have been found in the face, upper half of the body and in the region of the buttocks in one-third of the cases. These yellowish nodules may appear and disappear. Children in the later stages develop respiratory difficulties due to the fibrosis of the lungs, and the x-ray findings may resemble a miliary metastasis. Due to the induration in the pulmonic fields, there is an increase of the resistance in the circulation with right cardiac hypertrophy and accentuation of the second pulmonic tone.[3]

Prognosis.—The progress of the disease is slow and irregular with intervals of improvement. The milder cases take a prolonged course. Death often occurs between the second and fourth years of life as a result of respiratory complications, cardiac insufficiency or severe anemia.[3] According to Rowland children in the sixth and seventh years suddenly become obese and exhibit the typical picture of dystrophia adiposogenitalia. The mild cases may extend to middle life, and in older individuals the findings may be accidental. The mortality is about 30 per cent in adults[10] which is more favorable than carcinoma, and several individuals have survived one and two decades with and without treatment.[5]

Laboratory Findings.—The daily amount of urine in the presence of diabetes insipidus various from four to fifteen liters, of low specific gravity, 1.001 to 1.004. Occasionally transient[1] glycosuria with low sugar tolerance is noted, but no albumen.[3]

The blood during the progressive stage of the disease may show a moderate to marked increase of the cholesterol content which may be as high as 397 mgm. per 100 c.c. of blood. Hoefer states that the total fatty acids are above normal. During remissions the lipoid content is within normal limits.[3]

In the severe cases the red blood cells may be below 1,000,000, while in the milder cases a moderate hypochromic anemia with a red blood count of 3,500,000 to 4,500,000 per cubic millimeter and a hemoglobin content of 55 per cent may be present. The while blood cells vary between 7,000 and 2,300 per cubic millimeter, while at times there may be an increase in the eosinophiles and monocytes.[3]

X-rays of the skull reveal sharply defined, irregularly shaped defects of the bones with geographical outlines and without reactive bone formations.[1] All parts of the skull may be involved. According to Christian the skull looks like a moth-eaten piece of cloth.[2] Other bones may also be involved.

Diagnosis.—1. One should be mindful of the disease if there are bony defects, especially in the cranial bones, polyuria, polydipsia, exophthalmos, loosening of the teeth, dwarfism and dystrophia adiposogenitalia.

2. Bone defects, especially of the cranium, which are sharply delimited with a map-like appearance, are probably the most important characteristics of the entity.

3. The large foam cells with abundance of protoplasm and small dark nuclei are generally characteristic of the disease.[1]

Therapy.—Dietary treatment may be mentioned such as a diet consisting chiefly of carbohydrates, with moderate amounts of proteins and very little fats.

The diabetes insipidus may be influenced favorably by pituitrin medication and insulin. Thyroid extract has been used without much effect and Sosman reports that some cases have shown improvement by healing of the defects of the bone from x-ray therapy.[8] Thus we have no specific or definite therapy.

Case Report

Mrs. H. L. G., white and fifty years of age, was seen by us August 12, 1926. She was referred on account of a tumor of the right breast which was discovered on examination. She had also complained of insomnia and at time diplopia, associated with dizziness, of six weeks' duration; generalized headaches at intervals with a "whistling" sensation in the ears, for the same period of time; dull pain over the precordium at times, not related to exercise, and of variable duration. A rather marked complaint was a low backache of varying degree with difficulty in stooping and standing. The backache had been present since childhood, increasing in recent years. She had difficulty turning in bed and also was uncomfortable lying in bed. Over-exercise aggravated her backache and produced difficulty in standing erect. She had a sensation in the top of her head which she described as loose bodies, especially when stooping or leaning over. Associated with this was a dull bizarre pain over the top of the cranium.

Family History.—The mother had died from carcinoma of the uterus. Two maternal aunts also had died of carcinoma of the uterus.

Past History.—The patient is said to have had sleeping sickness as a child. She also had scarlet fever as a child without complications, and influenza said to have been complicated by peritonitis.

She had had a hysterectomy and appendectomy in 1919, and a hemorrhoidectomy in 1920. Her history otherwise was essentially negative.

Physical Examination.—The patient measured five feet eight inches in height and weighed 185 pounds. The temperature was 98.6 F., pulse 84, and the blood pressure registered 165 systolic and 110 diastolic in mm. of mercury. Her skin was dry and scaly. Tenderness was elicited in the right subcostal area but no masses were felt. A small firm mass was noted in the upper outer quadrant of the right breast. The pelvis showed no masses, and there were a few external hemorrhoids on rectal examination. There was noted tenderness on palpation over the right sacro-iliac joint with apparently normal motions of the spine.

Laboratory Examination.—The urine was normal on several occasions. The hemoglobin was 75 per cent, with 5,248,000 red blood cells per cubic mm., and the white blood cells numbered 8,000 and 9,300 per cubic mm. with a normal differential count.

X-ray studies of the lumbar spine and pelvis revealed destruction of the intervertebral disc between the 4th and 5th lumbar bodies. The left sacro-iliac joint showed a pronounced increased density with an abundance of striations present believed to be an osteoblastic metastatic carcinoma. There were noted small sharply circumscribed areas of rarefraction which were also interpreted as metastatic carcinomas of the frontal and parietal areas of the skull.

The mass in the right breast was removed under gas anesthesia without difficulty and was fairly well encapsulated. No further exploration was deemed advisable. She made an uneventful convalescence. The mass grossly was rather firm and of uniform consistency. On microscopic sections the interpretation was metastatic carcinoma probably hypernephroma, and Grade IV carcinoma of the adeno type, primary undetermined.

In August, 1930, she was again seen for reëxamination, with the same findings as before, but now she also had some tenderness in the jaw. The pelvis, on x-ray examination, showed the process to have extended into the acetabulum, and the skull showed the defects to be smaller.

In May, 1932, when seen again, she had gained eight pounds in weight, and her blood pressure was 180 systolic and 110 diastolic; the pulse was 100 per minute. The right pupil was larger than the left. She complained of tenderness and pain over the right sacro-iliac joint radiating to the right lower quadrant of the abdomen, increased by activity. The spine on x-ray showed no appreciable change. One year later she informed us she had had attacks of an unexplained intermittent fever, as high as 103 F.

In July 1934, her condition and findings were similar to the previous examinations. Inasmuch as there was no change, a review of the sections was undertaken, and the masses of foam cells were discovered. The paraffin block was again sectioned and studied, the portion examined containing the characteristic foam cells. The interpretation of the skull and lumbar spine was Paget's disease. The blood cholesterol was 167 mgms. per 100 c.c.

On July 11, 1939, her examining physician informed us her condition was as follows: the attacks of dizziness were infrequent but very severe, came on suddenly and persisted for two to three days. To obtain relief she found it necessary to lie on the right side with her eyes closed, wearing dark glasses and having the shades drawn. Associated with the above, was considerable nausea. She would see four or five objects, and the room would go around and around. She had no deafness or tinnitus. During these attacks she could not turn to the left without increasing her complaints. Headaches over the entire skull had been observed also during the past year.

Physical examination revealed a blood pressure of 175 systolic and 100 diastolic, she had had a recent operation on the left breast, but the pathology was not known. The eyes, nose, throat, chest, heart and abdomen appeared normal. The examination of the ears revealed no definite disease. X-rays made of the mastoid, petrous bone, skull, lumbar spine, pelvis and femur were interpreted as Paget's disease.

Summary.—A general consideration of Hand-Schüller-Christian's disease has been reviewed with a presentation of a case with lymph node involvement which has been under observation for fifteen years without much change, and which had previously been diagnosed as carcinoma and Paget's disease. The flat bones of the skull, the lumbar spine and ilia showed involvement. The etiology of the disease is not definitely known nor is the treatment. This again emphasizes the importance of biopsy and the review microscopically of the tissues removed at operation.

Acknowledgment is made to Dr. E. T. Bell, of the

Department of Pathology, University of Minnesota, and to Dr. Norman Johnson, for their coöperation and aid in this case.

Discussion

Dr. S. E. Sweitzer, Minneapolis: If the surgeons do not care to talk about this, I have a word to say about this patient of Dr. Hanson. These cases are interesting to the surgeon, the ophthalmologist, the internist, and the dermatologist. It shows the difficulty of making a diagnosis from the slides. The condition is closely allied to reticulo-endotheliosis, and Drs. Winer, Cummings and I wrote up a case two or three years ago. We did a biopsy and found the first slide looked like xanthomatosis, and later slides showed reticulo-endotheliosis. There was no involvement of the bones of the skull, and no diabetes. The child kept getting worse and finally died. Autopsy showed reticulo-endotheliosis of the pelvic bones and of the spine. Sections showed reticulo-endotheliosis in some places and other sections showed Hand-Schüller-Christian's disease as shown tonight.

There is something to remember about this condition —that is, we do not know much about it. It is closely allied to endotheliosis and we don't know much about that either. The only thing we can do is, when we find a case, to report it and study it. Both Hand-Schüller-Christian's disease and reticulo-endotheliosis may be phases of the same fundamental disease and have the same background.

Dr. Hanson: I should like to have Dr. Sweitzer's opinion regarding the disturbances of the reticulo-endothelial system with patients who manifest the yellowish xanthoma plaques of the skin; in other words, do they manifest general xanthomatous manifestations?

Dr. Sweitzer: I have seen hundreds and hundreds of those yellowish plaques under the eyes, and not one of they had any of these other conditions.

* * *

The meeting adjourned.

A. G. Schulze, M.D., *Secretary.*

Tuberculosis mortality acts something like a social barometer, rising during wars, and rising highest in the countries most affected by the war. It is difficult to prophesy what the present war will mean in increased tuberculosis mortality in the belligerent countries, but we may be sure that it will be once more a true barometer of disturbed social conditions. Countries which are making the greatest efforts, which are keeping their industries keyed up to the highest pitch, working their men the longest hours and reducing standards of living to the lowest levels are bound to suffer severely.—Frank C. Boudreau, M.D., *News Digest of the Milbank Memorial Fund,* (June) 1940.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

It is your life—Keep Healthy, Stay Young, Live Long. Max M. Rosenberg, M.D. Formerly in charge of Clinical Laboratory O. P. Department, Beth Israel Hospital, Clinical Assistant Internal Medicine, Beth Israel Hospital, Clinical Assistant Pediatrics, Gouverneur Hospital. 450 pages. Illus. Price, $2.50, cloth. New York: The Scholastic Press, 1940.

The endocrine function of iodine. William Thomas Salter, Assistant Professor of Medicine, Harvard Medical School, Associated Physician Thorndike Memorial Laboratory, Boston City Hospital. 351 pages. Illus. Price, $3.50, cloth. Cambridge, Mass.: Harvard University Press, 1940.

The 1940 year book of general medicine. Edited by George F. Dick, M.D., J. Burns Amberson, Jr., M.D., George R. Minot, M.D., S.D., F.R.C.P., Edinburgh and London, William B. Castle, M.D., A.M., M.D., (Hon.) Utrecht, William D. Stroud, M.D., and George B. Eusterman, M.D. 934 pages. Illus. Price, $3.00, cloth. Chicago: Year Book Publishers, 1940.

Clinical Pellagra. Seale Harris, M.D., Professor Emeritus of Medicine, University of Alabama, Birmingham; assisted by Seale Harris, Jr., M.D., formerly Assistant Professor of Medicine, Vanderbilt University, Birmingham; foreword by E. V. McCollum, Ph.D., Sc.D., LL.D., Professor of Biochemistry, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md. 494 pages. Illus. Price, $7.00, cloth. St. Louis: C. V. Mosby Co., 1941.

Strange Malady—The Story of Allergy. Warren T. Vaughan, M.D. 268 pages. Illus. Price, $3.00, cloth. New York: Doubleday, Doran & Co., 1941.

HUGH YOUNG; A SURGEON'S AUTOBIOGRAPHY. 554 pages. With over 100 drawings by William P. Didusch, and three color prints. Price $5.00, cloth. New York: Harcourt, Brace and Company, 1940.

Some ten years ago the author dictated for his children a brief story of his experiences as a boy on a Texas ranch, and also told them of those fighting men, their grandfathers. He states that after this purely personal document happened to come to the notice of Mr. and Mrs. Harcourt they gave him no rest thereafter until he began to write this autobiography. Then the question arose as to how much of his work as a urologist, on which he had spent most of his time and effort, should be included. His friends, as well as his publishers, advised him to tell the whole story; without it, important as it was, the picture would be incomplete and therefore untrue. Besides this, he argued, his work had been largely with afflictions about which

there was still much ignorance, among them some of the deadliest of diseases. Subjects that were once taboo are now freely discussed by the laity, so now was an opportunity to shed some useful light on them, which he decided to utilize. Chapter 6, 128 pages in length, captioned "Developing a Specialty," is devoted to this phase of his interesting career and is beautifully illustrated by drawings from the hand of William P. Didusch, the artist who has been responsible for the illustrations in the technical publications of the author over a period of years. This section of the book alone makes it unique among medical autobiographies.

The preceding chapters deal with the author's ancestry and childhood, his student years and those of starting to practice in Baltimore. A graduate of the University of Virginia he took some graduate work in Johns Hopkins and then secured an internship followed by a surgical residency in the Johns Hopkins Hospital. This was in the heyday of the Big Four, with whom he was thrown in close contact and his association with these well-known men affords him an opportunity to tell some delightful stories and give an intimate insight into their personalities. Osler and Halsted both had a keen sense of humor and were practical jokers. Perhaps this had its influence on the author, for the book teems with wit and light heartedness throughout. His earlier days were not easy, but he came of fighting stock and writes of his difficulties as easily and unconcernedly as with the restraint he applies to his successes.

His later years were full of action and interest. Happy in heart and in his daily life he never allowed himself to be enslaved by the problems or the demands of his professional work but gave freely of his time, thought and means to outside activities. He travelled, hunted and fished, learned languages, patronized art and music and through his professional contacts with people important in political life was able to influence the passage of public health measures in fields far removed from his own specialty. He was an early enthusiast in aviation.

With the outbreak of the World War and as it progressed he became increasingly incensed at Germany and felt strongly that we should prepare for war. He wrote articles on the necessity of military training in the *New York Times* and the *Baltimore Sun* during the winter of 1916-17 but saw no results, so he joined with a small group of professional and business men from Baltimore to present the matter in person to President Wilson, who listened to them without evidence of more than casual interest. Soon after our entry into the war the author went to Washington again and offered his services to the Surgeon General, who issued orders for him and three assistants to proceed to England at the earliest possible moment for special urological duty. How he complied with these orders constitutes one of the most amusing stories in the whole book. But this assignment led to the most far-reaching consequences imaginable: the institution of thorough-going measures for the prevention of venereal disease throughout the A.E.F.

At seventy Hugh Young can look back on a long life fraught with joy and usefulness. He concludes his delightful recital with these words: "Need I say more to show how much I have enjoyed the life I have led, or what a thrilling time I have had in my professional work? But there is still so much to do, so much to live for."

GILBERT COTTAM

A SURGEON'S LIFE; THE AUTOBIOGRAPHY OF J. M. T. FINNEY. J. M. T. Finney. 396 pages. Price, $3.15, cloth. New York: G. P. Putnam's Sons, 1940.

You will read every word, spellbound. You will not want any interruption when you read this book. Refreshingly stimulating and encouraging—just what you long for now—a personified human touch. A life with a goodly heritage. A race well won! Honors well deserved! Truly the author's lot has fallen in pleasant pastures.

Physicians, medical students, nurses, social workers, patients will want to read this book. The reviewer also whole-heartedly recommends its careful study and application by each member of the present-day medical schools' faculty admission committee members. This autobiography is a light unto the feet of him who aspires to make medicine his vocation.

LILLIAN L. NYE, M.D.

DO YOU WANT TO BECOME A DOCTOR? Morris Fishbein, M.D. 176 pages. Price $1.50. New York: Frederick A. Stokes Co., 1939.

Written for students considering the study of medicine, this book contains a brief discussion of present-day medical education with emphasis on the difficulties of modern curricula. Premedical requirements, costs of medical education and a brief description of each Class A medical school are included. Ten pages are devoted to a discussion of the internship. Special discussion is made of problems peculiar to the Jewish student and to the colored stunt. There is a brief discussion of the specialties, the accessory professions and the future of medicine. The book is brief, well organized and well written.

While presenting an excellent summary of the field covered and containing much valuable factual information, the impression is that for the serious student who may be in a real dilemma on choosing a profession the book doesn't quite get down to business.

CHAS. C. COOPER, M.D.

UNRESTING CELLS. R. W. Gerard, Associate Professor of Physiology, University of Chicago. 439 pp. Illustrated. Price, $3.00. New York: Harper and Brothers, 1940.

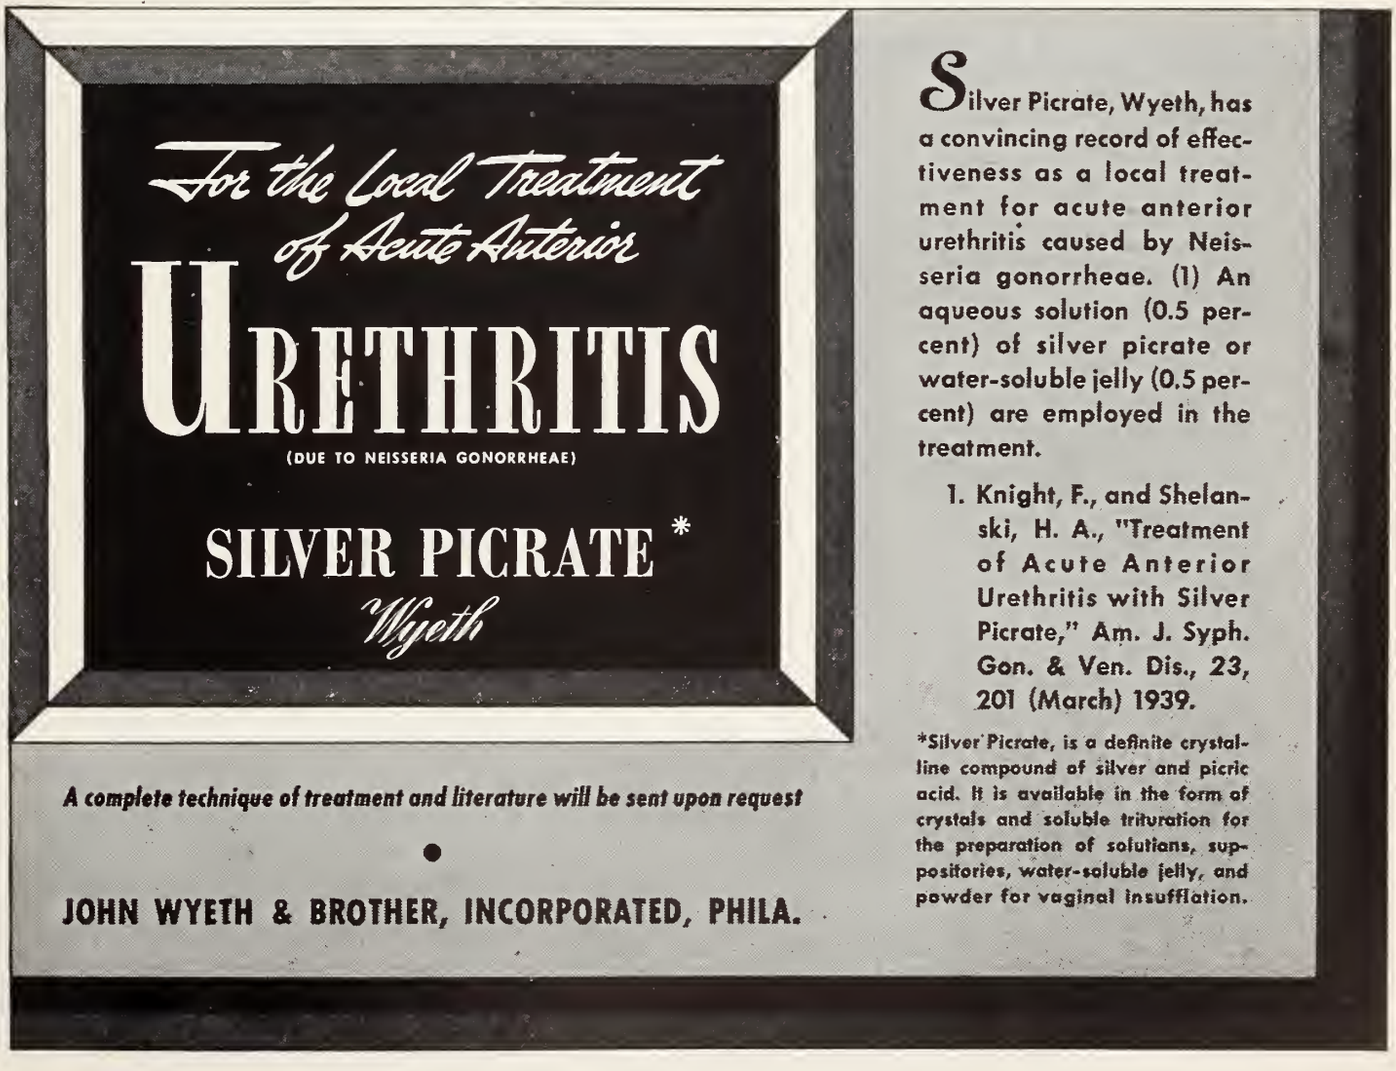
This is a most unusual book. During the past ten years knowledge of cell chemistry, cell membrane structure, enzyme nature and action, muscle action, chromosome nature has advanced in astounding fashion. It seems fantastic to suppose that knowledge here gained can be presented with detective-story interest. Gerard has done just that. Secrets of funda-

mental processes within the cell are being learned; cell physiology is no longer an uncharted domain in science. How enzymes do their work, how the chromosomes can multiply and direct cell structure, how the fertilized egg can develop varying cell types —these have been perennial mysteries. The author gives a perspective view of the present concepts on these and other subjects of medical interest: some relations of antibodies, enzymes, hormones, vitamins, of viruses and crystals; the processes of cellular oxidation and anabolism; body oxidases; high points of cellular membrane physiology. The book is brief, has an absorbing style, contains many diagrams well designed to gain clarity. It is highly recommended for the physician who desires knowledge of recent concepts on fundamental processes he sees in the life about him.

C. J. Potthoff, M.D.

THE COMPLEAT PEDIATRICIAN—PRACTICAL PEDIATRICS. Third Edition. Wilburt C. Davison, M.A., D.Sc., M.D., Professor of Pediatrics, Duke University School of Medicine, and Pediatrist, Duke Hospital. 256 Sections. Price, $3.75, cloth. Durham, N. C.: Duke University Press, 1940.

It is indeed a pleasure to again be able to present gleanings and impressions of Dr. Davison's splendid work. The author has admirably succeeded in presenting this third edition as a text of practical value in diagnosis and teaching, by emphasizing symptoms and signs as clues, rather than description: a wonderful step forward from the former method of teaching—mechanical memorization of textbook descriptions of disease.



In this edition, 10,000 lines were changed because of the accumulation of additional pediatric information during the past three years. The author very generously expresses his thanks and appreciation to those who so ably rendered assistance. The reviewer notes with congratulations and pride the inclusion of Dr. A. T. S. Davison.

The author has listed the abbreviations used in the text under Instructions. A new paragraph heading, Unproven Remedies, appears. Prognosis is given prominence. This edition, more clearly by large type, simplifies the ready classification.

The reviewer suggests that a text, so very fine—with no equal in the field—receive more cautious proof reading and crictical pre-press scrutiny, particularly in the reference numbers and text content referable to the Index and Drug Sections; also a more extensive and a more detailed, explicit Drug and Prescriptions Chapter; a more complete laboratory presentation of newer, much used methods.

This text, together with each of the author's other editions, well deserves a place on every physician's desk. We shall await the appearance of the fourth edition in 1941.

Lillian L. Nye, M.D.

MANAGEMENT OF THE CARDIAC PATIENT, William G. Leaman, Jr., M.D., F.A.C.P. Assistant Professor of Medicine in Charge of Department of Cardiology, Woman's Medical College of Pennsylvania; Cardiologist Woman's College, Memorial, Northeastern Hospitals and Philadelphia Hospital for Contagious Diseases, etc. 705 pages. Illus. Price $6.50, cloth. Philadelphia: J. B. Lippincott Co., 1940.

Many books on heart disease have been published in the past few years. This one is distinguished by the fact that it deals mainly with treatment. The author discusses each major type of heart disease by first presenting a brief resumé of the pathology, diagnostic signs, and treatment. The treatment is further elaborated by the use of illustrative cases which are in turn discussed by the author. In addition to chapters on the classic types of heart disease such as rheumatic, hypertensive, coronary, etc., there are sections devoted to the heart in pregnancy, allergy and the heart, cardiac emergencies, diet and physiotherapy in the treatment of heart disease, and the use of social service. There is also a chapter on the electro-cardiogram.

The outstanding contribution of this book is the presentation of the treatment of cardiac disorders through the method of illustrative cases. This technique, together with the author's discussions, gives the reader a very practical insight. This book will be appreciated most by those physicians who wish a practical guide to the management of heart disease.

Wm. D. Coventry, M.D.

INTRODUCTION TO BIOCHEMISTRY. W. R. Fearon, M.A., Sc.D., M.B., F.I.C., Dublin. 2nd edition. 475 pages. Illus. Price, $3.75. St. Louis: C. V. Mosby Co., 1940.

This book is very clearly written in the almost typical British outline form by which the vast amounts of information can be written in a rather small volume. The pure biochemical considerations are very complete and are interesting in that a considerable amount of emphasis is placed on the chemistry of inorganic matter in relation to general physiologic chemistry. The consideration of inorganic chemistry is usually minimized in most American biochemical texts. I feel, however, that the book lacks correlation with the physiologic processes as they occur in the body and for this reason it is quite difficult to follow the general trend of the text. The sequence is purely chemical.

This book should find wide acceptance among teachers and students of physiologic chemistry *per se*, but it lacks applicability to the needs for chemical information sought by the practicing physician and medical student.

MINERAL METABOLISM. Alfred T. Shohl, M.D., Research Associate in Pediatrics, Harvard University. American Chemical Society Monograph Series. 384 pages. Price, $4.50, cloth. New York: Reinhold Publishing Corporation, 1939.

The two-fold purpose served by these monographs, to present the knowledge available in an intelligible, understandable form and to promote research through the context's well-digested survey of the up-to-date progress and through suggested avenues of investigation, is well fulfilled in this text. Every one interested in the field of mineral metabolism will profit by reading this presentation, both from the laboratory and clinical standpoints.

Lillian L. Nye, M.D.

TRICHOMONAS VAGINALIS IN THE MALE

(Continued from page 110)

In addition there were quite a few pus cells and also live trichomonas vaginalis. His wife had been examined by an excellent gynecologist, but no trichomonas vaginalis were found in her discharge. The urine was acid, sp. gr. 1030, very faint trace of albumin, a few r.b.c., an occasional w.b.c., full of mucus and calcium oxalate crystals, but no trichomonas vaginalis were found. I ordered a condom specimen which was brought three-quarters of an hour after coitus and after four days' continence. The specimen was not brought in a condom however but in a rubber finger because, as previously mentioned, he never ejaculates though he has orgasm, but about ten minutes later a thick mucoid ejaculation appears at the meatus, and it was this specimen brought in a rubber finger which I examined. The specimen showed very many lively spermatozoa. I never saw such lively spermatozoa and they acted as if something was chasing them. Even hours later and without any special precaution they were still found to be exceedingly lively. The specimen itself was much thicker than ordinary semen, but this did not in any way interfere with the motility of the spermatozoa. A careful search, moreover, did not reveal the presence of trichomonas vaginalis in this specimen. As the patient made no further visits after this examination, it was impossible to make any further studies of this interesting condition.

PRELIMINARY REPORT OF THE SPECIAL OTTER TAIL COUNTY TUBERCULOSIS SURVEY*

Summer, 1940

L. J. WEBSTER, M.D.

Superintendent, Otter Tail County Sanatorium
Battle Lake, Minnesota

THE major field project of the Otter Tail County Sanatorium in 1939 was the Mantoux testing of the high school students of the county. During the year, 1,416 school children from the seventh through twelfth grades were Mantoux tested. A total of 124 children who reacted positively were x-rayed, and those children known to have a positive Mantoux from previous surveys and still in school were re-x-rayed. No cases of tuberculosis requiring treatment were found. It is the writer's conception that a sanatorium is not only a hospital for the care of a limited number of patients, but it should be an institution whose function is the control of tuberculosis in the area which it serves. In the control of tuberculosis, it must not only treat tuberculous individuals in an attempt to get them well, it must prevent the development of tuberculosis which, as in other diseases, is the goal to be attained. Tuberculosis being a contagious disease, there is only one way of preventing it, and that is by the discovery and isolation of every active open case. In 1939 the sanatorium had not accomplished its function, the major field project had been high school Mantoux surveys, and with these surveys not a single case of tuberculosis had been discovered.

An analysis was made of the Sanatorium admissions for the year 1939. Of the seventeen admissions which were cases previously unreported, twelve, or 70 per cent, were classified as far advanced, four, or 23 per cent, as moderately advanced, and only one as in the minimal stage. Obviously those with far and moderately advanced disease had had tuberculosis for some time and a different case finding program might have found some of them in an earlier stage. On further analysis of all the Sanatorium admissions for the year 1939, a total of 33 patients, sixteen, or 48 per cent, were found to be individuals who had been previously treated in tuberculosis sanatoria in whom the disease had again become active; and eleven others, or 33 per cent, gave a history of tuberculosis having existed at some previous time in some member of the immediate family. These two groups totaled 81 per cent of the admissions for the year. If the disease had again become active in some former patients, was it not possible that it had become active in others who had not come up for examination? If members of the immediate families of some of the old cases of tuberculosis were now developing tuberculosis, was it not possible that members of the immediate families of other old cases were also developing tuberculosis? It appeared that making the examination of reported cases and their families, the only project in field work for 1940 would reveal not only cases of active open tuberculosis, but also cases of tuberculosis in minimal stages even before symptoms became apparent, thus detecting and making possible the healing of incipient cases of tuberculosis before they became infectious.

To examine old cases and their families is not a new method of case finding. The Sanatorium in Otter Tail County has always carried on such a program as part of its field work. The only

*Read at the Minnesota State Sanitary Conference, November 29, 1940, Minneapolis.

change proposed was that all the available time and funds, both of which were very limited, be devoted to this one project.

Dr. H. G. Lampson,[4] reported in 1915 that:

1. "A very large percentage, 79 per cent, of the individuals fully exposed for a long period of time to open cases of tuberculosis became infected.
2. "A much smaller percentage, 28 per cent, of those partially exposed or exposed for a short period of time became infected.
3. "The percentage of infections from casual exposure, such as everyone encounters, was small—8 per cent.
4. "The more frequent infections of children may be explained, at least in part, by their more intimate contact with the patient.
5. "At all ages the intimacy and length of exposure are the determining factors in infection with tuberculosis."

Dr. David Zachs[7] found that two out of every three children who exhibit grave tuberculous lesions of the adult type came from families that show a tuberculosis morbidity of 41.7 per cent and a case mortality of 49.1 per cent, and he concluded that "these considerations point to the family relationship as a source of greatest danger in childhood and youth." H. R. Edwards[2] states: "The examination of the exposed contacts to tuberculosis should logically reveal more new tuberculosis than the examination of any other group, and experience everywhere confirms this if the source case has been known to have bacilli in the sputum. . . . The adult contact is more likely to reveal new manifest disease than the child." In mass surveys carried on under his direction since 1933 in the City of New York, 162,446 individuals from fifteen population groups were x-rayed and 4 per cent were found to have reinfection tuberculosis, 2.5 per cent being clinically significant, i.e., active. One of the population groups consisted of 16,810 college students, only .3 per cent of whom were found to have reinfection tuberculosis, only .2 per cent clinically significant. Another population group consisted of 15,795 high school students, with .4 per cent found to have reinfection tuberculosis, and .4 per cent clinically significant. All other population groups consisting of adults showed higher percentages than either of these. In a study conducted by Edwards and Unzicker[3] in New Haven, Connecticut, they reported that the actual cost of finding a new case of pulmonary tuberculosis by the examination of the contacts of cases of tuberculous meningitis was $78.00, by the examination of the contacts of cases of pulmonary tuberculosis $140.51, and by the examination of the contacts of children with positive Mantoux tests it was $1,063.50. F. T. Lord[5] states that in Massachusetts they have found one child in every 700 high school children examined to have adult tuberculosis. The cost of finding one case averages $1,000.00.

To make the examination of reported cases and their family contacts the only project meant, of course, that the Sanatorium must omit the other activities which it had previously carried on as a part of its field work, and the question was therefore discussed with the local medical society and the Otter Tail County Public Health Association. Both groups offered their enthusiastic support. Since funds and personnel were both limited, a very modest program was proposed. Fortunately, Dr. A. J. Chesley, of the Minnesota Department of Health, heard of the program and offered the assistance of the Minnesota Department of Health. Dr. Hilbert Mark, Epidemiologist in tuberculosis in the Division of Preventable Diseases, Minnesota Department of Health, was assigned to this survey. Funds for the purchase of x-ray films and for the employment of an x-ray technician and a clerk were made available from Social Security Funds through the Minnesota Department of Health and the Division of Social Welfare of the Department of Social Security. Through the coöperation of the Sanatorium Commission and the Otter Tail County Public Health Association, the Sanatorium field nurse was freed from her routine duties and assigned to the survey.

As one part of the survey, it was planned to examine all individuals with tuberculosis now living in Otter Tail County. The list of cases reported to the Minnesota Department of Health from Otter Tail County was used as an index. The registration of cases began in 1913 when tuberculosis was made a reportable disease. Since in 1939 about 19 per cent of persons dying from tuberculosis had not been previously reported as having tuberculosis, it was recognized early that the Minnesota Department of Health lists were incomplete, and local sources were used for clues to unreported cases. The other part of the survey was the examination of the members of the families of all reported cases of tuberculosis who were still living in the county. In locating the original

reported case, or if he was not available, his family, a visit was made to the postmaster, the physician, the health officer, the village or town clerk, and the old settlers in the locality of his last known address. A visit was then made to the home of the reported case, or his closest kin, and two forms were completed, one for the family, and one for the patient. The reported patient was given an appointment for an x-ray, and, if expectorating, two sputum specimens were collected for cultural study. His family, except for those known to have a positive Mantoux test from previous examinations, were requested to report at a Mantoux clinic in one of eight cities and villages selected for holding Mantoux clinics. Adults (except a few who presented themselves later than on the first day of each of the clinics) were given an initial Mantoux test with a 1:10,000 dilution of Old Tuberculin and if negative in forty-eight hours the examination was repeated with a dilution of 1:100. The 1:10,000 dilution was used first on adults since it was felt that a significant number of adults would react to this weaker solution, and in that way avoid painful local reactions which might possibly occur with an initial test of 1:1,000 dilution. The 1:100 dilution was chosen for the second test dose since it was known from studies at the University of Minnesota Medical School[1] that some 10 per cent more would react to a dilution of 1:100 than to 1:1,000, and it was felt that a test with the 1:100 dilution would not produce an inordinately severe reaction in adults negative to the 1:10,000 dilution. All children under twelve were given an initial test with a dilution of 1:1,000, and most of them were not retested. Adults who came to the clinic after the first day of testing were given one test with a dilution 1:1,000. All tuberculin used was Old Tuberculin freshly diluted for each clinic and furnished by the Minnesota Department of Health. All those found to have a positive Mantoux and all family contacts with a previously known positive Mantoux were given an appointment for an x-ray at the Sanatorium. Practically all the x-ray films were sent for reading to the roentgenological staff of the University Hospital, and every x-ray which exhibited evidence of reinfection tuberculosis was sent to them for confirmation. The report of the x-ray was made in writing to the family physician of the individual in each instance, together with recommendations insofar as tuberculosis follow-up was concerned. No reports were given to lay individuals.

The survey has now been completed in the eight areas into which the county was divided. In the county a total of 1,605 individuals had been reported from 1913 to the summer of 1940 as having tuberculosis. Of these, over 900 had died, nearly 200 had moved out of the county, over fifty were in some one of the several institutions in this state for the care of the tuberculous, about 100 could not be located, and there were an even 200 still living in the county. To date, 164 of the 200 remaining in the county have reported for examination, of whom twenty-one were found to have active open tuberculosis, and again in need of sanatorium care.

Field investigations revealed 698 family groups having a history of familial exposure to one or more cases of tuberculosis still residing in those areas. The term, family group, as used in this survey, more closely approximates an epidemiological unit than a family. Supposing two brothers had tuberculosis, and that each was married, with a wife and children. The family group in that case would consist of their father, mother, brothers, sisters, and each one's wife and children, three different families which make up the one family group. In these 698 family groups, 3,867 individuals were found residing in Otter Tail County. All of the 3,867 individuals except those with previously positive Mantoux tests were asked to attend the nearest Mantoux clinic. Of these, 1,522 presented themselves for Mantoux tests, and 765 were positive. At present, figures are not available on persons known to have had positive Mantoux tests previously and who were not retested at the clinics. Altogether 1,168 family contacts with positive Mantoux reactions have been x-rayed, and fourteen supposedly healthy persons were found to have active reinfection tuberculosis requiring sanatorium care. Six, or 45 per cent, were minimal, three, or 21 per cent, were moderately advanced, and five, or 35 per cent, were far advanced.

It is interesting to compare this with the previously unreported cases admitted to the Sanatorium in 1939. In 1939 only one new patient was admitted with a minimal lesion, 6 per cent of the seventeen previously unreported cases admitted.

An additional forty-four individuals were found to have reinfection tuberculosis, which ap-

pears inactive on x-ray but which will require further study to definitely determine activity.

The cost of the survey may be subdivided under the following headings:

Visits in the field, including salaries, travel expense, etc.	$3,296.86
Mantoux clinics salaries	399.75
X-ray expense, including salaries, x-rays, developing, etc.	1,195.20
Clerical expense, including salaries, postage, supplies, etc.	679.04
Total	$5,570.85

The cost as listed above is the total cost. No charge was made for interpretation of x-rays by the University of Minnesota Hospital staff. Included in the cost, however, is a proportionate share of the salaries of all regular Sanatorium employes who devoted part time to the survey, though their salaries were continued by the Sanatorium.

An estimate made by the Eastman Kodak Company[6] at Rochester, New York, as a result of a survey among 100 tuberculous employes disclosed that the average cost per individual for diagnosis, treatment, examination of contacts, and time lost from work was $4,000. The cost of the completed survey in this county is $5,570.85.

It is difficult to state the cost per case discovered because the survey consisted of two parts: (1) the examination of previously reported cases of tuberculosis; and (2) the examination of their family contacts. It is impossible to determine what proportion of the total cost should be applied to each group. In addition, some of the cases found are clinically unimportant and perhaps should not be considered. If one considers only the fourteen cases of active tuberculosis found among the family contacts, and divides the total cost by fourteen, one finds the cost per case to be $397.91. If one considers all the reinfection tuberculosis discovered among the family contacts, whether active or apparently inactive, a total of fifty-eight cases, one finds the cost per case to be $96.05. If one considers the fourteen cases of active reinfection tuberculosis found among the family contacts and the twenty-one cases found to again have active tuberculosis in the group of previously reported cases, a total of thirty-five, one finds the cost per case to be $159.14. If one considers all types of cases discovered, that is, the fourteen active and the forty-four apparently inactive reinfection tuberculosis in the family contacts, and the twenty-one found to again have active tuberculosis in the group of previously reported cases, a total of seventy-nine cases, the average cost is $70.52.

Could such results be duplicated in other parts of the state? Is Otter Tail County unusual in any respect? It is a large county of sixty-two townships, with a population in 1930 of 51,006. Sixty-five per cent of the population, 33,246 people, live in rural areas. There is only one city, Fergus Falls, with a population of 9,389, and seventeen villages, eleven with a population under 500, four with a population between 500 and 1,000, and two with a population between 1,000 and 1,500. There are only 107 individuals of races other than white. Of the whites, 84.5 per cent are native born, 15.5 per cent foreign born.

The Sanatorium was built in 1913 and it was the second county sanatorium established in the State of Minnesota. Through education, the people of the county have gradually come to accept the services of the Sanatorium. In the five-year period, 1915-1919, there were 183 people who died of tuberculosis in their homes, 69.5 per cent of the 263 deaths from tuberculosis. In the five-year period, 1935-1939, only twenty-five people died from tuberculosis in their homes, only 33.8 per cent of the seventy-four deaths. The morbidity and mortality rates from tuberculosis have been steadily falling, and the county has a record as good as the state average. In the five-year period 1915-1919, 429 people were reported as having tuberculosis; in the five-year period, 1935-1939, only 143 were reported, exactly one-third. In 1915-1919, there were 263 deaths from tuberculosis; in 1935-1939, only seventy-four, less than one-third. The average mortality per 100,000 in Otter Tail County in the five-year period, 1935-1939, was 29.01. The mortality in the state as a whole in 1939 was 30.2. That is a record to which Otter Tail County can point with pride. But, it was still possible to find thirty-five cases of active tuberculosis requiring sanatorium care. Is Otter Tail County unusual?

If such a survey as is in progress in Otter Tail County is considered valuable, and if such surveys are to be carried on in other parts of the state, how are they to be financed? Such a survey would not have been made in Otter Tail County without the assistance of the Minnesota Department of Health and the other coöperating

groups. Should not the counties make more funds available for such inexpensive case finding? The state provides financial assistance to the counties in the care of their indigent tuberculous patients by defraying a portion of the sanatorium cost. Should not the state also subsidize case finding programs? If the state should bear part of the cost of case finding programs, should its contribution be in the form of personnel temporarily assigned to the institution, as is the case in the present survey, or should its contribution be a cash subsidy to the institution for the partial support of the institution's own program? Will funds be made available by the state to partially meet the cost of continuing such surveys? After all, in the present survey less than one-third of the 3,867 family contacts, and only about eighty-two per cent of the 200 reported cases living in the county have been examined. In 1935, the State Board of Health, in accordance with recommendations of the Advisory Committee on Tuberculosis, submitted to the Legislature for its consideration a request for funds to aid the various sanatoria and the State Board of Health in such work.

For several years in this state there has been doubt as to the efficacy of the present sanatorium set-up for the control of tuberculosis. It has been felt that some of the smaller institutions have out-lived their usefulness and might possibly be replaced by larger district sanatoria; that tuberculosis has so decreased that it is impossible to keep the beds filled. It has been felt that these institutions, being small and in many cases not fully equipped, are unable to give adequate modern treatment for tuberculosis, treatment which in recent years has laid more and more emphasis on surgical procedures. If funds were available for more adequate case finding programs we would find in most areas in Minnesota that we would not have too many beds for tuberculosis, but too few. A small institution cannot offer as complete and adequate medical service to its patients within its own walls as may a larger institution, but in most cases the necessary additional treatment is easily available to the patients of small institutions by their referral for short periods to more adequately equipped institutions. More adequate case finding programs should result in the discovery of a larger percentage of minimal cases of tuberculosis. These minimal cases, as they do not require the facilities of the large institution in their treatment, could be cared for as well in small institutions near the patients' homes, and much of the need for new large institutions might disappear.

A sanatorium logically acts as a case finding center for the area which it serves. Before we decide to abandon the small institution now giving a concentrated case finding program to a small area of one, two, or three counties, we should be sure that the new plan for the control of tuberculosis will make at least an equally adequate provision for case finding in these areas.

A preliminary report of the tuberculosis case finding survey in Otter Tail County has been presented. Of 164 previously reported cases examined, twenty-one again were found to have active, open tuberculosis. Of the family contacts of previously reported cases, 1,168 persons were x-rayed. Of these, fifty-eight were found to have reinfection tuberculosis; in fourteen the lesions were definitely active, and the individuals were in need of sanatorium care; the lesions in forty-four appeared inactive but further study of these individuals is necessary. The importance of an adequate case finding program in tuberculosis has been emphasized, and the rôle of a small institution in such a program outlined.

Family life in contact with a case of tuberculosis greatly increases risk of the infection spreading, especially in the age group when health is of maximum economic and social importance.—George H. Ramsay, M.D., et al., *Health News,* Oct. 21, 1940.

COCCIDIOIDAL GRANULOMA: A BRIEF REVIEW WITH REPORT OF A CASE OF MENINGEAL INVOLVEMENT*

WINCHELL McK. CRAIG, M.D. and MALCOLM B. DOCKERTY, M.D.
Rochester, Minnesota

FOR the past fifty years the study of pathogenic yeasts and fungi has held the attention of the botanist, the medical mycologist, the dermatologist, the medical internist, the surgeon and the pathologist. Years of research have brought to light many interesting observations on the life cycles of these lowly pathogens. Early difficulties in classification and identification of species gradually have been overcome and the pathologic lesions peculiar to the individual fungi elucidated. Among these pathogenic fungi, the coccidioides holds a prime position from the pathologic and mycologic standpoints. In addition, the disease it produces in man has a peculiar geographic distribution.

Historical Aspects

Wernicke, in 1892, described a case of dermatitis with abscesses encountered in Buenos Aires from which protozoan-like organisms were obtained. Death occurred and in 1900 Posadas gave a detailed account of the lesions. In the meantime (1894 and 1896) Rixford and Rixford and Gilchrist reported instances of a similar fatal infection occurring in two California laborers. Among the numerous and important contributions of these two early investigators were the observations that the organisms were spore forming in the lesions, that they elicited tissue reactions similar to those produced by the tubercle bacillus, and that rabbits were susceptible to inoculation by material from human lesions.

Although they noted a resemblance between the organism they described and the known fungus of blastomycosis, these investigators believed they were dealing with a protozoan (coccidioidal) infection. Stiles, a medical mycologist, named the parasite "Coccidioides immitis." That the parasite was in fact not a protozoan but a pathogenic mold was shown by Ophüls[9] in 1900. From material obtained in a case encountered by him this investigator demonstrated that the organism could be grown on artificial culture media and that it grew as a mold with the production of white mycelia. He classified it with the oidia, but suggested that out of respect to Rixford and Gilchrist the generic name should be retained. He proposed the designation "Oidium coccidioides" for the organism. Clinically he recognized cutaneous, pulmonary and mixed forms of the disease and he believed that the lungs as well as the skin were frequently the portal through which infection entered. Pathologically, he postulated that the sporulating form of the organism, seen only in tissue lesions, was merely one phase in the life cycle of the mold. Dickson, in 1915, reviewed the literature and found reports of forty cases of coccidioidal granuloma. He remarked at that time that thirty-five of these had been observed in California and that twenty-seven of these had been residents of or visitors in San Joaquin Valley. He gave 90 per cent as the mortality rate in the generalized form of the disease.

The condition by this time had become known as California disease. Many cases were reported in the literature and many valuable contributions were made by Moore, Benham, Meyer and others on the life cycle of the organism. In 1929, Dickson[3] showed conclusively that infection did occur via inhalation of chlamydospores produced in the vegetative phase and that the incubation period was about nine days.

In the period from 1929 to 1938 this same author made a discovery which startled the medical world and opened up a new field for the study of coccidioidal infection. For years the residents of the San Joaquin Valley had experienced epidemics of what was locally named valley or desert fever. This self-limited illness took the form of a severe influenza-like infection of the upper part of the respiratory tract with chills, fever, cough and expectoration. In 80 per cent of the cases within eight to fifteen days of the onset lesions simulating those of erythema nodosum appeared on the extremities. These lesions faded after four to five days; cough and other symptoms cleared up usually in three to four weeks. Dickson cultured sputa from a num-

*From the Division of Neurosurgery (Craig) and the Section in Surgical Pathology (Dockerty), The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota Surgical Society, Duluth, Minnesota, October 4, 1940.

ber of these cases and found coccidioides in more than 70 per cent. In only one out of more than 350 cases of valley fever observed within a period of eighteen months did the disease progress to the stage of generalized dissemination. This patient died of coccidioidal meningitis.

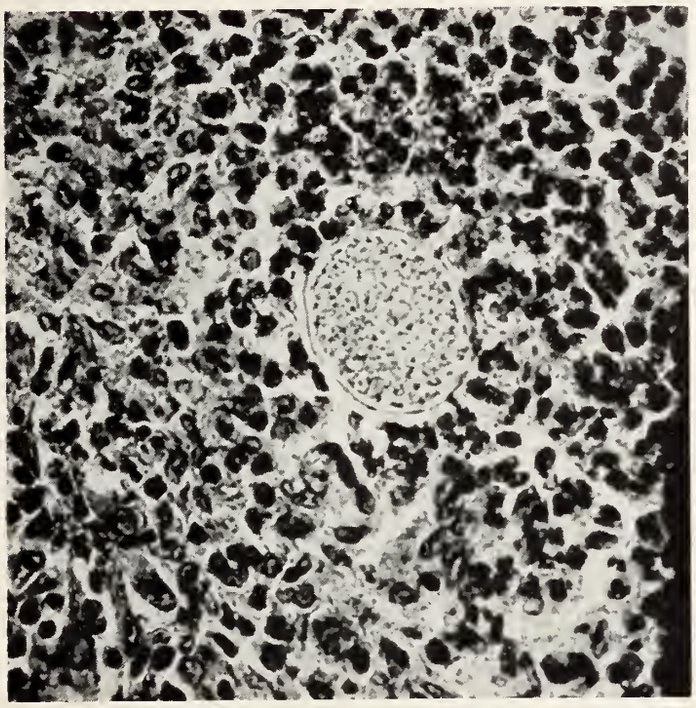

Fig. 1. Large oval doubly contoured and spore filled organism, Coccidioides immitis from specimen removed from the brain at operation. The acute inflammatory exudate forming a micro-abscess may be noted (hematoxylin and eosin, x475).

That valley fever is only one manifestation of coccidioidal disease is an observation, the importance of which cannot be overestimated. It serves to emphasize more than ever the peculiar geographic localization of the disease, its high morbidity and relatively low mortality rate when considered in all its phases, and from the standpoint of lack of immunity it explains perhaps why visitors to the San Joaquin Valley run special hazards of developing the granulomatous form of the disease. Coccidioides appears to be endemic in other localities, namely, Colorado, New Mexico, Brazil and the Argentine. However, doubt has recently been thrown on the authenticity of cases reported from South America. Of the many recorded cases of coccidioidal infection from South America Moore accepted only two. The remainder he considered as being caused by the organism Paracoccidioides, a fungus more closely related to the organism of blastomycosis than to Coccidioides immitis.

The general mortality rate of the disease including the cutaneous form and excluding valley fever is approximately 50 per cent.[18] At necropsy the lungs are practically always involved but almost every organ of the body has at one time or another been reported as the seat of metastatic lesions. Apparently both the blood and lymph participate in the general dissemination. In all of the seven cases[4,10,12,15,17] (including the one to be reported) of involvement of the central nervous system which have been reported in the literature the disease was fatal; basilar lesions have been present in all instances and in several meningeal involvement of the cervical portion of the spinal cord.

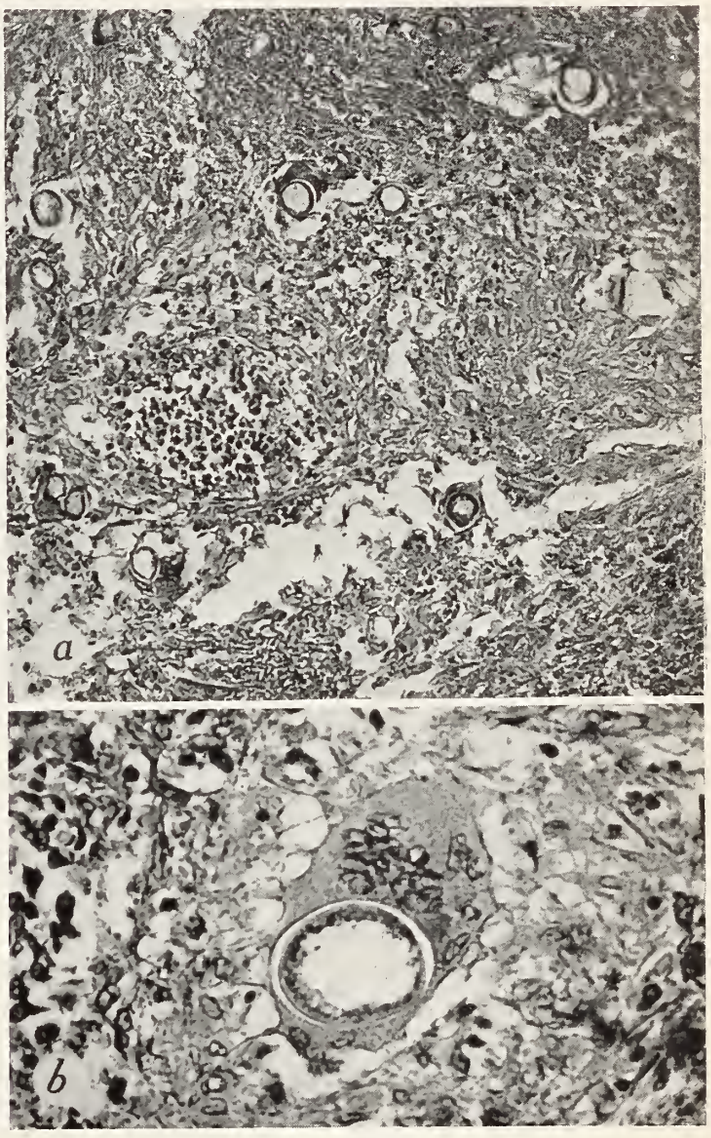

Fig. 2. Lesion from lung; *a*, coccidioidal organisms and surrounding chronic inflammatory reaction with numerous giant cells and moderate fibrosis in a nodular lesion from the right lung. The resemblance to tuberculosis is apparent (hematoxylin and eosin, x140). *b*, The coccidioidal organism within a giant cell (hematoxylin and eosin, x400).

The diagnosis of coccidioidal granuloma is usually made in the laboratory, either from a study of smears or sections of accessible lesions, sputum, and so forth, or by means of culture. In some cases the coccidioidin skin test furnishes additional evidence, but as pointed out by Dick-

son, aggravation of symptoms may follow the subcutaneous injections of any but minute doses of the toxin. The matter is being further investigated.

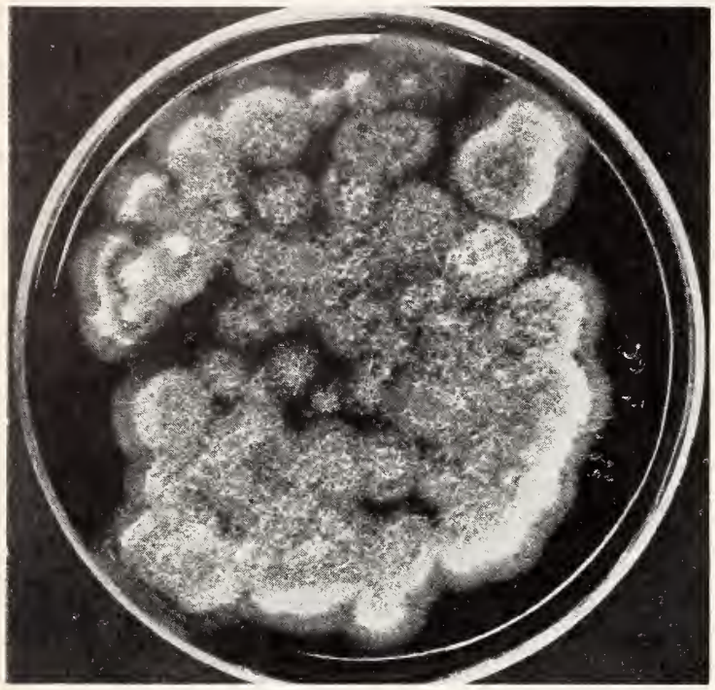

Fig. 3. Ten-day growth of coccidioides from infected brain. The colonies appear "fuzzy."

Treatment is unsatisfactory as a study of mortality statistics and a review of the numerous and varied remedies that have been tried indicate. Perhaps future investigation will confirm the findings of Jacobson whose coccidioidal vaccine employed in a series of twenty-four cases gave a number of apparent cures. All of Jacobson's patients survived except two who had meningitis.

Report of Case

The patient, a man aged forty-nine years, who had always lived in Iowa, registered at the Mayo Clinic on May 9, 1940, and gave a history that he had spent a vacation of two weeks in southern California in March. On April 25, which was about a month after he left California, mild occipital headaches developed. They were dull and throbbing and fairly constant except that they were worse in the morning. The headaches were made worse by bending over, but there was no extension of pain down the neck and no stiffness of the neck. A few days after the onset of the headache, he began to notice a dull ache about the left eye, and following consultation with an eye, ear, nose and throat specialist, his antrum was lavaged without any relief of pain. Five days before admission to the clinic the pain became intense, and he was confined to bed. As long as he lay quietly, he was fairly comfortable, but the minute he arose, the pain became very severe. Projectile vomiting occurred the day of his admission.

Neurologic examination gave essentially negative results except for marked incoördination of the patient's hands and arms. Spinal puncture was done; the Kolmer and Kline tests on cerebrospinal fluid gave negative results, and the values for globulin and

Fig. 4. The mycelia from the culture shown in Figure 3 with hyphæ and chlamydospores.

total protein were within normal limits. There were a few lymphocytes and a few polymorphonuclear leukocytes. Examination of the cerebrospinal fluid threw no light on the nature of the condition, but immediately after the spinal puncture the headache became much worse, Cheyne-Stokes respiration occurred, and the patient appeared quite sick.

The patient was hurried to the operating room, a bur hole was made quickly, and the right lateral ventricle was drained. The fluid was under moderate pressure, although the examination of the eyes had revealed no evidence of papilledema. Immediately following the relief of pressure, respiration became quieter, and his condition improved. The next day he felt fairly well, and we were able to reëxamine him. The only positive finding was the persistent incoördination. Our impression was that we were probably dealing with a tumor of the fourth ventricle, as we have seen patients with these tumors react in a similar way to examination and spinal puncture.

The spinal puncture was done on May 11, and on May 14, under ether anesthesia, with the patient in the upright position, bilateral cerebellar craniotomy and decompression were performed. The fourth ventricle contained no evidence of tumor. However, in the upper outer quadrant of the left cerebellar lobe at a depth of about 2 cm. a mass was found. When the cortical vessels were ligated and the cortex was divided with an electrosurgical unit down to the tumor, we thought we were dealing with a fairly well circumscribed gliomatous mass. When a portion was removed for biopsy and diagnosis from a frozen section, there was a gush of seropurulent material which at first seemed to be mucoid in nature. The brain was quickly protected and the entire mass was removed. At

first, this mass seemed to be neoplastic although it was associated with a great deal of inflammatory reaction. Examination of the frozen tissue suggested an abscess of unknown origin, and the contents were sent for culture. The lesion was treated as an abscess with drainage, and chemotherapy was instituted immediately. Fixed sections of the lesions, which will be described later in this paper, revealed Coccidioides immitis, and evidently we were dealing with coccidioidal granuloma of the brain.

During the entire illness the patient's temperature was elevated a little. The catheter left in the lateral ventricle for drainage drained large amounts of cerebrospinal fluid; when it was clamped off, the headache returned. This led us to believe that occlusion of the aqueduct of Sylvius was present and probably due to ependymitis. The patient was conscious, quite clear mentally, and if we had not known the etiology of his condition, we would probably have thought he was improving.

Sulfanilamide, sulfathiazole and other chemotherapeutic drugs were used without effect. At the end of four weeks his condition seemed about the same except for some marked drowsiness, although he could be aroused with difficulty. Suddenly on June 13, 1940, he had difficulty in breathing, acute respiratory embarrassment developed and death occurred.

TABLE I. TISSUE DIAGNOSIS: DIFFERENTIAL POINTS

Organism	Disease	Reaction	Cellular products	Budding	Spores	Distribution of lesions
Blastomyces * dermatitidis	Blastomycosis	Acute, with polymorphonuclear neutrophils	None	Always	Never	Skin and generalized (lungs especially)
Coccidioides immitis	Coccidioidal granuloma	Acute, with polymorphonuclear neutrophils	None	Never	Always	Skin and generalized (lungs especially)
Debaryomyces neoformans	Torulosis	Mild chronic	Mucoid material	Sometimes	Never	Usually in brain, meninges

*The fungus "Zymonema dermatitidis" has been named by some as the etiologic agent in blastomycosis. However, because absolute proof of this is lacking, Henrici and others are in favor of retaining this older term, manifestly inaccurate, but justified on the basis of usage.

TABLE II. LABORATORY DIAGNOSIS: DIFFERENTIAL POINTS

Organism	Disease	Organisms in culture			Pathogenicity for animals
		Mycelia	Ascospores	Colonies	
Blastomyces* dermatitidis	Blastomycosis	Always	Never (?)	Dry and fuzzy	Slight or absent
Coccidioides immitis	Coccidioidal granuloma	Always	Never	Dry and fuzzy	Marked for all laboratory animals
Debaryomyces neoformans	Torulosis	Never	Recently demonstrated	Moist (mucoid)	Marked for rats and mice; slight for guinea-pigs (principally brain lesions)

*See footnote on Table I.

Pathology

The surgical specimen, received from the operating room, on staining with polychrome methylene blue, presented at once the features of an acute inflammatory process. Occasional giant cells were seen and tuberculosis was con-

sidered as a possibility although the acuteness of the inflammatory process seemed rather unusual. Study of fixed frozen sections stained with hematoxylin and eosin revealed an acute and subacute inflammatory reaction with micro-abscesses. Within these tiny abscesses were seen round to oval doubly contoured refractile bodies varying in diameter from 8 to 15 microns. Occasional lanceolate forms were observed. Most of these bodies were completely filled with minute round spore-like structures (Fig. 1). In some instances these granular masses had ruptured through the capsule of the mother cell and spilled into the surrounding tissue. Occasional giant cells were encountered; some had engulfed the large organisms but in most instances the latter were seen in the midst of collections of polymorphonuclear leukocytes. Budding and the "spine" forms of the organism described by Benham and others were not observed.

At necropsy the material of interest consisted of the brain and the lungs. In the former, around the operative site, the inferior pole of the left cerebellum, and the lining of the fourth ventricle a purulent inflammatory exudate was visible grossly. The left cerebellar hemisphere was the seat of an abscess 1 cm. in diameter. Cerebral edema and hydrocephalus were superadded as a result of blocking of the passage of cerebrospinal fluid.

Both lungs contained multiple indurated grayish red nodules with caseous centers. These nodules were scattered throughout both lungs and had the gross features of chronic but active tuberculosis. No other gross lesions were observed.

Microscopic examination of the lesions of the brain presented the picture previously described. The pulmonary lesions proved not to be tuberculous but were nodules of coccidioidal granuloma. They appeared older than the cerebral lesions by virtue of a more chronic inflammatory reaction with many foreign body giant cells (Fig. 2*a* and *b*). This finally fitted in with the well recognized fact that the primary lesion of coccidioidal granuloma is frequently pulmonary. The results of cultures from the lesions are clearly shown in Figures 3 and 4 and need no special comment. Even without guinea-pig inoculation the diagnosis of coccidioidal granuloma was the only one fitting the recorded facts of the case. For a brief summary of the classic features which served to distinguish the closely allied conditions of blastomycosis, coccidioidal granuloma and torulosis, Tables I and II, modified from Benham, are appended.

Summary

A short account is given of the history of Coccidioides and the geographic distribution of the disease which it causes. In our case of coccidioidal granuloma the symptoms were the result of intracranial involvement, but the primary lesion was of pulmonary origin. The infection was almost certainly acquired by the patient during a brief sojourn in southern California.

ANATOMY, PHYSIOLOGY AND SURGERY IN DUODENAL STASIS*

F. C. SCHULDT, M.D., F.A.C.S.
Saint Paul, Minnesota

Report of Case

J. E., a man aged twenty-five, had suffered since childhood from epigastric distress, nausea, a full feeling for some hours after eating, and a great deal of belching. There also was abdominal pain present. These symptoms all were at their worst when he was in the upright position; while in the reclining position he was a great deal easier. He was especially distressed after eating wieners, cold slaw, and highly seasoned foods. As long as he can remember he became nauseated or vomited when riding in a street car or train. As a railway mail clerk, he vomited many times while on duty. This simulated sea sickness, but was accompained by a bloated feeling. At this time an x-ray examination by Dr. Schons of St. Paul revealed, under the fluoroscope, a back and forth churning of the food column in the horizontal portion of the duodenum. A diagnosis of duodenal stasis was made. The patient was then placed on a lengthy medical regime.

An appendectomy had been done in 1931. The symptoms were not relieved by the removal of the appendix.

In June, 1937, the patient had improved under medical care and bed-rest, but as soon as he again went about his activities, he had the same misery. On September 18, 1937, he entered St. Joseph's hospital where another x-ray examination showed the same findings as before; no evidence of ulcer or carcinoma of the stomach or ulcer of the duodenum. There was quite a marked dilatation of the duodenum together with reverse peristalsis and churning of the food column in the right sided portion of the duodenum.

I first saw the patient who was referred by Dr. J. Lepak, on September 22, 1937. Operation was advised as the x-ray diagnosis was definite and a medical regime was insufficient to permit the patient to work.

On September 23, 1937, the operation was done under spinal anesthesia. Upon close examination of the third portion of the duodenum I found that by telescoping the jejunum into the duodenum that two fingers readily passed into the lumen. This convinced me that there was no intrinsic disease of the duodenum. I was impressed, however, by the embarrassing mechanical situation consisting of a narrow slit-like communication between the third and fourth portion of the duodenum. There was a formidable barrier to the patency of the tube due to extrinsic pressure of an overlying band of fat, containing the superior mesenteric artery and vein. The two entering fingers could readily lift this barrier but that was more lifting power than could be exerted by the peristaltic wave and besides the patient was in the supine position, in which there was less drag on the artery. A side to side duodeno-jejunostomy was made. The first two postoperative days required duodental tube suction. After that the convalescence was uneventful and on the fifth day the patient sat up in the chair feeling well.

Four weeks later he reported, "The former distress is gone, I have no sour stomach and no distressing belching."

Four months later an x-ray examination was made of the stomach and duodenum and we saw a duodenum with a normal lumen and the food passing through the recently made stoma.

In a letter of February 1, 1939, the patient stated, "I now enjoy good health for the first time in my life."

He now weighs 15 pounds more then he had ever weighed before.

Comment

The anatomic arrangement of this area in man is rather interesting and it becomes even more fascinating when comparing it to the anatomy in animals. In man the superior mesenteric artery leaves the abdominal aorta at an acute angle and extends caudally. At the apex of this angle is the left renal vein and next caudally is the duodenum. The superior mesenteric artery supplies the jejunum, ileum, cecum, ascending colon, hepatic flexure and the right one-third of the transverse colon. It is apparent that two or three hours after a meal there is in the upright portion a considerable drag of the small intestine and the right portion of the transverse colon due to gravity. These patients are greatly benefited by the horizontal position or the knee chest position simulating the quadruped.

The veterinarian speaks of this area of the anatomy as the anterior and posterior mesenteric artery. The anterior mesenteric artery in the animal has a different direction. The acute angle made by the superior mesenteric artery with the abdominal aorta in man does not exist in the animal. Incidentally, the close proximity of the anterior mesenteric artery to the duodenum is the probable cause of the transmission of the trypanasome, Stronglyus vulgaris, into the artery causing a fatal aneurism of the anterior mesenteric artery. This is a common disease among

*Read before the Saint Paul Surgical Society, Saint Paul, Minnesota, October 10, 1940.

horses and mules in the tropics and to some extent in the temperate zone.

The technic of x-ray studies of the gastro-intestinal tract up to a few years ago has consisted in visualizing the barium column descending in the esophagus, its entrance into the stomach, the

Fig. 1. X-ray appearance of the duodenum before operation.

careful scrutiny of the stomach itself and then the pylorus and the first portion of the duodenum. Our interest as a rule ended here. Occasionally the following x-ray pictures would reveal a duodenal diverticulum but we missed the fluoroscopic visualiziation of the food column in the duodenum. As soon as there is reverse peristalsis in the pars horizontalis of the duodenum the patient experiences a nausea. Much of the nausea patients complain of may have its origin in the duodenum. Mal de mer, street car or train sickness may have reference to a mild degree of duodenal stasis. Mal de mer sufferers as a rule are able to partake of food and are fairly comfortable lying flat on their back in their cabin.

The duodenum which normally has the widest lumen of the small intestine takes on added lumen dimension and probably increased thickness of its wall in this condition. Normally the food column after its passage through the pylorus fills the duodenal cap where it pauses a few moments and then in rapid glides flows uninterrupted through the rest of the duodenum into the jejunum.

Pool et al.[6] stress the need for exacting fluoroscopic examination of the duodenum in all cases in which there is any suspicion of difficulty. They describe the phenomenon "producing an abnormal puddling and cradling of barium in the dependent loop."

In the preparation of a patient for duodeno-

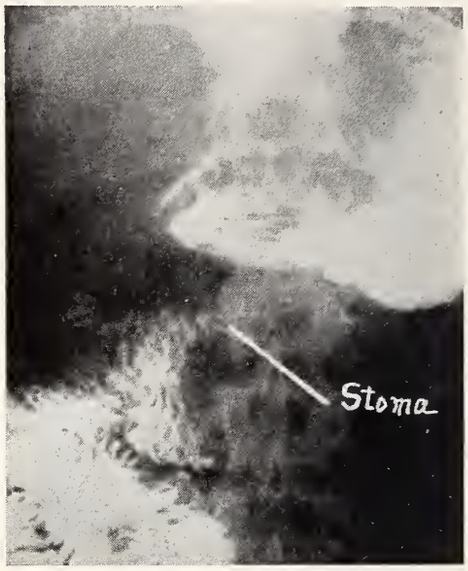

Fig. 2. X-ray appearance of the duodenum after operation.

jejunostomy, it is advisable that a duodenal suction tube be passed before the operation as usually the stomach in these cases is so ballooned that it adds to the difficulty of the operation on the duodenum.

As to harmful consequences, Portis[8] reports, "It is well known that if allowed to go unchecked, these changes may result in severe toxemia. These changes manifest themselves in a drop of the plasma chlorides, a shift in the acid-base balance and the non-protein nitrogen of the blood."

Water, glucose, alcohol, potassium chloride, and sodium chloride can be absorbed by the duodenum.[8]

The term "abdominal neurosis" is a condition which is often associated with temporary delay in the duodenum.[8]

Brown[2] feels that "the upright position of man has brought about the difficulty because in animals the duodenum hangs free on a mesentery."

Earl[3] reports good surgical results in patients who do not respond to medical regime.

Duodenal stasis has been found to be associated with duodenal ulcer. Medical care is advised by all authors, as a great many patients are sufficiently benefited to be able to continue

their work.[4,1] The medical regime consists of any one of the following: rest in bed in the supine position from four to six weeks, duodenal lavage and feeding, the knee chest posture after meals, elevation of the foot of the bed and a well fitting abdominal support.

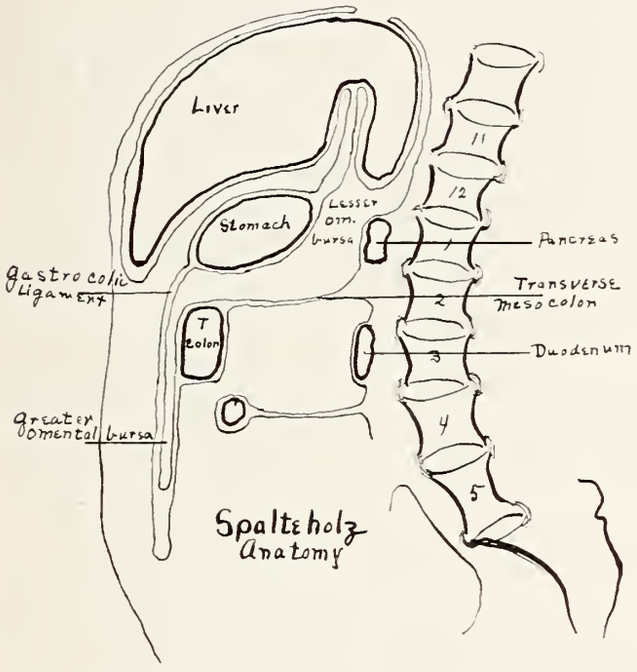

Fig. 3. Late embryonic stage of development of the omentum.

If the supine position does not produce results the prone position with a pillow support under the chest and pelvis, leaving the abdomen free, should be tried.

A variety of operations had been performed on a great many of these patients with no relief, indicating that the true condition had not been recognized.[7]

"The clinical symptoms are heaviness and fullness after eating, nausea, dizziness, a sea sickness, fatigue, headache, palpitation, irritability, insomnia and anxiety."[7]

Dr. Béla Halpert[5] of Prague has done some very extensive work on the anatomy and physiology of the duodenum and I shall borrow from him freely.

The detailed anatomical division of the duodenum is as follows: pars horizontalis superior from pylorus back and to the right; the flexura duodeni superior dextra; the pars descendens; the flexura duodeni inferior dextra; the pars horizontalis inferior; the flexura duodeni sinistra; the pars ascendens; and the flexura duodeni jejunalis.

The radix mesocolica divides the duodenum into pars superior and pars inferior. The radix mesenterii divides the duodenum into the pars dextra and pars sinistra.

The inferior pancreaticoduodenal artery and the median colic artery, as a rule, together with six jejunal arteries leave the superior mesenteric

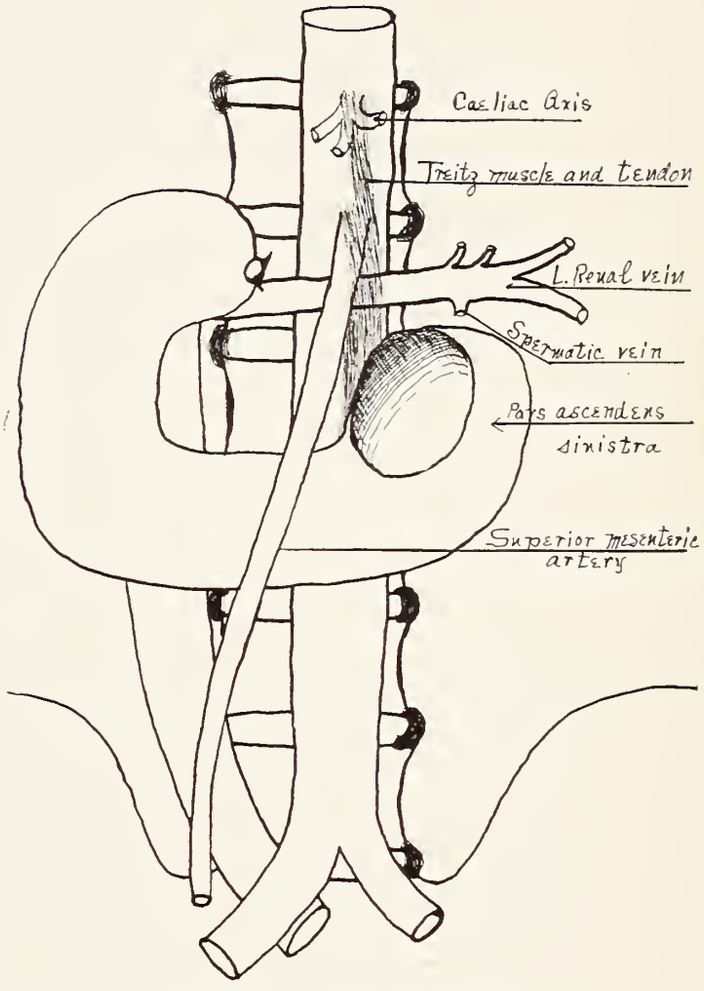

Fig. 4. Normal anatomy of the duodenum, left renal vein, artery superior mesenteric and ligament of Treitz.

before it comes to the point of duodenal compression. The mesenteric root containing the mesenteric vein and the now reduced mesenteric artery cross the distal horizontal portion of the duodenum where it crosses at the level of the body of the third lumbar vertebra.

Although the mesentery has a sufficient length to permit even normally the small intestine to rest in the pelvis, yet when there is a duodenal stasis present, we find that the mesentery of the small intestine lying in the pelvis following a meal exercises a sufficient pull to flatten the duodenum against the tense aorta.

The pars horizontalis inferior duodeni crosses the lumbar vertebræ at the level of the third lumbar while the superior mesenteric artery has its origin from the aorta at the level of the first

lumbar. As to the etiological factors of duodenal stasis, Halpert emphasizes the point that on the basis of a study of 300 autopsies he found that this condition can happen only when there are definite peritoneal abnormalities.

It is apparent that when a stretch is made on the mesentery of the small intestine, the angle of the superior mesenteric artery with the aorta becomes more acute. The direct pressure thus exercised would come first upon the left renal vein which occupies the very apex of the angle.

In these cases of duodenal stasis, Halpert also found an orthostatic albuminuria. The albumin would disappear with the patient in the horizontal position. He makes the observation that in the standing position the lumbar spine becomes more lordotic and together with the anatomical position of the renal vein in the acute angle of the superior mesenteric artery and aorta, plus the mesenteric drag in the standing position there is a compression of the left renal vein which produces passive venous congestion of the left kidney causing an albuminuria.

An erroneous diagnosis of nephritis can readily be made in such a patient. An orthostatic albuminuria could be used as an aid in the differential diagnosis of a high placed duodenal ileus.

Halpert has made further observations regarding anomalies:

1. There may be five renal veins on the left side.
2. There may be two veins, one passing in front and one behind the aorta.
3. Often the only left renal vein passes behind the aorta.

Sonne (quoted by Halpert) declares that inasmuch as the left renal vein is longer than the right and must pass over the aorta in the acute angle formed by the superior mesenteric artery and the aorta it must in addition pass over the lordotic lumbar spine and the thus constituted stasis of the kidney is the cause of the albuminuria.

Rieser (quoted by Halpert) is under the impression that orthostatic albuminuria is caused by compression of the left renal vein due to the fact that the superior mesenteric artery and the aorta act like a pincher upon the vein either because of a lordotic effect on the aorta or a tightening of the mesenteric cord.

Anatomically the right spermatic vein enters the vena cava directly. The left spermatic vein enters into the left renal vein. By the same process of compression causing stasis of the left kidney, we can also have the stasis extending into the spermatic or ovarian vein, causing a varicocele in the pampiniform plexus in the left scrotum or a varicose condition of the pampiniform plexus of the ovary on the left side.

In two case reports of acute dilatation of the stomach clinically diagnosed as pyloric stenosis, Halpert found at autopsy a hugely dilated stomach filled with fluid, and an overstretched pylorus with the duodenum equally tense up to the position where the superior mesenteric artery crosses it. The mesentery resembled a tense cord. A knot of small intestine lay deep in the right small pelvis. The small intestine was entirely empty up to the point where the superior mesenteric artery crossed the duodenum. At autopsy he experimented by lifting the knot of loops out of the pelvis, relaxing thereby the cord-like mesentery and immediately the impounded fluids rushed through the compression area and filled the, up to now, empty loops.

A typical picture of postoperative gastric dilatation, Halpert's first case had been diagnosed nephritis because there had been considerable albuminuria. But this was an orthostatic, lordotic albuminuria due to compression of the left renal vein which was pinched or compressed in the acute angle of the mesenteric artery and aorta. The abnormal course of the renal vein between the third lumbar vertebra and aorta, at the vertex of the lordotic curve of the lumbar vertebra, may also cause stasis of the left renal vein. In the horizontal position the lordotic curve is less, pressure is relieved and the stasis and albuminuria are corrected.

The superior mesenteric artery arises from the aorta at the level of the intervertebral disc between the first and second lumbar vertebrae. Immediately above this position is the celiac axis. Originating from these two first unpaired vessels of the abdominal aorta are tendonlike fibers passing downward with some muscle tissue, the Treitz muscle. The tendon fibers then spread out and attach themselves to the musculature of the pars ascendens duodeni. This causes the duodenum to be a fixed organ and there is no way that it could evade the pincher pressure of the mesenteric root.

Halpert recites the developmental peritoneal abnormalities as follows:

1. A high mobile cecum.
2. A short ascending colon.
3. A long transverse colon.
4. A long transverse mesocolon.
5. A deficient ligamentum hepatico colicum.
6. A second peritoneal attachment between liver and hepatic flexure.
7. A deep inferior omental recess due to a lack of union of the anterior with posterior surface of the greater omentum.

If these two peritoneal surfaces fail to unite, there is an absence of the gastrocolic ligament. The absence of this ligament together with the incomplete hepaticocolic ligament, which are the structural support of the colon, cause the transverse colon to sink deep into the lower abdomen. This brings about an increased pressure on the mass of small intestines.

Waldeyer (quoted by Halpert) points out that the transverse mesocolon, extending from the posterior abdominal wall to the tenia of the transverse colon, constitutes a partition between the upper and the lower abdomen, or divides the glandular abdomen from the intestinal abdomen.

The clinical case here reported represents a mild or moderate deviation from normal physiology. It helps to explain some of the types of nausea or sea sickness or car sickness which have no pathologic basis. Never shall I forget the comfort I once gained when suffering from mal de mer by lying supine and pillowless.

The cases described by Halpert are the advanced or completed picture which rapidly lead to a fatal issue.

Summary

1. A duodenojejunostomy corrected both clinically and radiographically the distressing symptoms due to a duodenal stasis.

2. In cases with peritoneal abnormalities there is a pinching or compression effect exerted upon the left renal vein and the pars horizontalis inferior duodeni by the superior mesenteric artery, mesenteric vein and mesenteric cord.

3. This is not a strangulation but a compression of the duodenum which causes a duodenal stasis. It may cause an acute dilatation of the stomach which may be fatal.

4. The same pressure on the left renal vein causes a left kidney congestion with orthostatic-lordotic albuminuria. Also it may cause a left-sided varicocele in man and left pampiniform varicosities in the ovary.

A REPORT ON PROGRESS IN ADRENAL THERAPY*

J. LAWRENCE McLEOD, M.D.
Grand Rapids, Minnesota

THE remarks I am about to make do not advance anything new or revolutionary on the subject but in them I shall attempt to review the late advances, and condense into form usable by the general practitioner knowledge which is not in general use. The subject was selected because of a severe case of Addison's disease which it has been the privilege of our group to follow and on which we have received aid and advice from Dr. E. L. Tuohy, and the Duluth Clinic staff.

Mrs. L. G., aged forty-eight, a cook at the farm school, had been seen by us at intervals since January, 1939. She is the mother of three children, the youngest twenty years old. She reported that when she carried him she had a severe influenza and after he was born she never menstruated again. There was

*From the Itasca Clinic, Grand Rapids, Minnesota. Read before the annual meeting of the Northern Minnesota Medical Association, Duluth, Minnesota, July 19, 1940.

no past history of tuberculosis or contact with anyone having it. Her Wassermann reaction was negative.

When we first saw her she complained of marked asthenia and tiredness especially severe in the morning but she had carried on her regular work. Her skin and mucous membranes demonstrated a mild but definite pigmentation which had come on very gradually but uniformly since 1935 but had at no time worried her or her family. She had no loss of weight.

Her previous life had been healthy except for periodic attacks of nausea and vomiting which had occurred once or twice each year for about twenty years. Various physicians had diagnosed these spells as food intolerance, indigestion, enteritis, gallbladder colic and iron deficiency.

Our general examination was entirely negative. Her blood pressure taken many times varied from 120 to 144 systolic and from 80 to 90 diastolic, her urine was negative, her blood picture was normal with a hemoglobin of 100 per cent and fasting blood sugar of 172. Her blood picture in 1935 taken elsewhere had been: Hgb. 75 per cent, r.b.c. 4,000,000, w.b.c. 14,400, but in the meantime she had taken ferrous sulphate intermittently.

We made no diagnosis. In May, 1939, she had a spell of marked nausea and vomiting, chills, fever and backache which lasted one day and when we saw her we were content to agree with her that some food indiscretion had upset her.

In November, 1939 her continued weakness led to a check-up by the Duluth Clinic and a diagnosis of Addison's disease. The positive symptoms were progressive asthenia, amenorrhea, pigmentation and syncopal gastric attacks. It is to be noted that normal blood pressure and maintenance of average body weight present in this case do not rule out Addison's. When one realizes that a patient with Addison's disease has often arrived at the autopsy table without any pigmentation at all or that pigmentation may occur five to six years before any physical symptoms appear and when normal blood pressure readings can persist long after the disease is active, one can appreciate the diagnostic pitfalls. It is interesting to note that at Duluth also her blood pressure was found normal, varying from 126 to 140 systolic. Her blood and urine examinations as already reported were normal. Several estimations of sodium chloride in the blood were made and these varied from 380 to 400 mgs. per cent The method of Dr. Wilder and associates for testing sodium chloride urinary excretion while the patient was on a high potassium intake was carried out. The findings were in keeping with the clinical manifestations, viz., whereas the sodium excretion dropped quite low it was not low enough at any time to institute clinical symptoms. The lowest blood pressure was 116 systolic. The diagnosis then rested principally on the asthenia and pigmentation.

The patient returned to us, remained on a high salt diet, was given plenty of extra vitamins and reported moderate improvement. Suddenly the afternoon of April 11, 1940, she became extremely ill with marked dyspnea, nausea, then severe vomiting, great weakness, headache and chills. When I saw her, the extreme dyspnea, chills and temperature of 102° made me wonder whether pneumonia was not impending. Palliative measures during the night failed and she was admitted to Itasca Hospital 8:30 a.m., April 12, 1940, and a diagnosis of crisis of Addison's disease was made, although her blood pressure still remained from 112 to 120 systolic.

Prior to 1922 and the advent of insulin the physician frequently sat by the bedside of a patient in diabetic coma and wondered if the day would ever come when medicine would conquer death from that case. On April 12 we stood beside a comatose patient with a normal blood sugar and urine suffering from an extreme Addisonian crisis and recalled the words of Dr. Roundtree in the Encyclopædia of Medicine of recent date—"Coma is not uncommon and recovery from it is rare. In many cases the last days of life are spent in what seems to be a restless sleep."

Without definite standards such as we now have in diabetes to guide us, we commenced intravenous medication, using normal saline and 10 per cent glucose with adrenal cortex extract, then more concentrated salt and more extract. Our patient became markedly cyanotic and her respirations assumed the Cheyne-Stokes type before we got any response and she started to rally.

In the first twenty-four hours she got 18 c.c. of adrenal cortex extract and twenty-six grams of salt intravenously plus adrenalin as a cardiac stimulant and 2,000 c.c. of 10 per cent glucose. She remained restless and at times delirious but always completely comatose.

The second twenty-four hours we gave 12 c.c. of adrenal cortex extract and twenty-seven and one-half grams of salt intravenously, continuing adrenalin and glucose as needed. During the afternoon of this day she seemed semi-conscious and aware of people about her.

The third twenty-four hours we gave her 13 c.c. of adrenal cortex extract and 37.5 grams of salt by intravenous route. Her respiration and pulse approached normal, toward the end of the night she became conscious and her general improvement was very similar to that of a patient recovering from a diabetic coma.

Each day after that we gave her 5 grams of salt plus as much as she could tolerate in her food with 9 c.c. of cortex extract the fourth day and 6 c.c. on the fifth and sixth days. Her recovery at this stage was without untoward event and she was discharged her eighth hospital day on 2 c.c. of cortex extract and about 5 grams of salt.

We had successfully brought our patient through her crisis. What of the future for her? In four days we had used adrenal cortex extract which cost thirty-two dollars. Such expensive treatment would make its continuous use prohibitive.

Fortunately biochemists have been at work.

There is now available a synthetic product which appears to furnish the essential hormone.

Let me first quote a brief historical sketch reported by Wilder:[4]

"In the course of the last ten years a successful major offensive has been made on a medical front which formerly seemed impregnable. The brunt of the campaign has been borne by investigators in the laboratories; the application of the advances made by them is the subject of the following account. The time is appropriate to review this past experience, because today, unless all signs fail, the knowledge and the means are at hand for a reasonably effective treatment of adrenocortical insufficiency, and until very recently, although steadily improving therapeutic results had been obtained, the disease defied us.

"Before 1930, when Swingle, Pfiffner and others provided active adrenocortical extracts, the mortality figures for Addison's disease were staggering. A few patients who were fortunate enough to have only partial destruction of adrenal tissue might live several years, but a large majority died within a few months and none could stand unusual stress of any kind.

"The extracts of adrenal cortex helped enormously. Patients in the shock-like state known as crisis, which before that time had almost always been a fatal event, could be restored to life. However, all such extracts were weak in activity and also frightfully expensive. The volume of material necessary was larger than could be given without great discomfort, and the cost, for any but the very rich, was prohibitive. Therefore, the ultimate results of treatment remained unsatisfactory, as Snell's report in 1934 made clear. On the basis of his data only seven of forty-six patients were alive more than a year after obtaining extracts.

"Then, in 1934, came the knowledge contributed by Loeb and confirmed by others, as well as our laboratories, that administering extra salt was beneficial, and soon thereafter the information came from several sources, that dogs maintained with salt after adrenalectomy excreted more sodium than chloride. If this was compensated for by giving mixtures of sodium chloride and sodium citrate, so as to provide more sodium than chloride, the patterns of electrolytes and concentration of urea in the plasma of adrenalectomized dogs remained normal.

"The clinical application of these facts was established promptly by observation of patients. It was found that they could be sustained more effectively than before, and with less adrenal extract, if they were given not only sodium chloride but also sodium citrate. We administered daily about 10 gms. of the former and 5 gms. of the latter. The salts were dissolved in a liter of water, artificial fruit flavoring was added and the solution was served iced under the inviting label of 'Addison's Elixir.'

"Another year passed, and the importance of controlling the intake of potassium was recognized by Allers, Nilson and Kendall. This information was applied in the hospital, where accumulating evidence soon revealed that as small an intake of potassium as 4 gms. a day, an amount no greater than that provided by general diet, would provoke excessive excretion of sodium and precipitate symptoms of Addison's crisis if patients were not receiving cortical extract. The same patients could be maintained with greater security than ever before and with still less, and in many cases no cortical extract, when the intake of potassium was limited to 2 gms.

"Administration of extra salt and sodium citrate and limitation of potassium greatly improved our clinical results, so that by July, 1937, Rynearson, Snell and Hausner could report that twenty-four of forty-three patients who received treatment between 1933 and 1937 were alive and in better condition than the surviving patients in the series reviewed by Snell in 1934. All of the individuals in the series reported in 1937 did not have the advantages of all the newer knowledge. Those that had died included many who had come to the Clinic before the diets low in potassium had been introduced.

"Results of the treatment of patients with Addison's disease continued to be as good as or better than those reported in 1937 until, early in 1939, when use of the crystalline preparation, desoxycorticosterone acetate, was begun at the Clinic. The brilliant work of Steiger and Reichstein made this available synthetically in 1938."

Since its discovery much therapeutic experimentation has been carried out by Thorn and Firor[3] at Baltimore; McCullagh[1] and Ryan at Cleveland and others using this synthetic crystalline cortical hormone which is manufactured by Schering under the trade name of Cortate and by Ciba as Percortin. This substance is now available in two forms: (1) in sesame oil for intramuscular injection where 1 c.c. represents 5 mgs. of desoxycorticosterone acetate; and (2) in pellets for subcutaneous implantation, each pellet containing 125 to 150 mgs. of the hormone and permitting an absorption of .25 to .35 mgs. daily.

The Baltimore men now have a good series of cases in which they have used the implantation method, putting from two to sixteen pellets under the skin after standardizing the patient on 4 to 8 gms. of sodium chloride daily plus a maintainence hypodermic dose of the hormone in oil. The Cleveland men have utilized the hypodermic method in all but one case and they seem to feel that they are getting a satisfactory response in a smaller number of cases using substantially the same amount of added salt daily.

In the case of our patient we obtained from Schering through Dr. Stoner three 150-mgm.

pellets of this experimental cortate and following the Baltimore technic implanted one pellet in the subcutaneous tissue of the infra scapular region. Eight days later, because the patient complained of the chair and her clothes rubbing it, I removed the pellet and replaced it together with a second one under the skin of her anterior abdominal wall. She is having no trouble now and, taking about 3 gms. of added salt daily, is doing her daily work as cook.

In the *Journal of the American Medical Association* for June 29, 1940, there are three articles, the Baltimore and Cleveland ones referred to above and one by Dr. Rowntree[2], now of Philadelphia, who reports six cases successfully treated exclusively with a non-commercial extract of the adrenal cortex, ignoring entirely the synthetic hormone. His final paragraph states:

"To me, whose experience with Addison's disease has been unusually large, these results represent the best I have seen to date. In years gone by, the care of patients with Addison's disease was fraught with constant anxiety. Formerly, patients were more or less continuously in a crisis, while now they are active, ambulatory, in moderately good health and going about attending to their daily business. In this series of patients crises have been prevented to a large extent and control of the hormonal deficiency has been effective. No toxic effects from treatment have been noted at any time in any of these patients, and local irritation has been entirely lacking. With the regimen outlined, the disease has been greatly ameliorated; remissions have been prolonged, complications rare and crises decreased in frequency and severity; rehabilitation has been striking and the survival time markedly increased. The last six consecutive patients on this regimen have averaged almost seven years of survival no deaths. From these results it is evident that true and nearly five years under this form of treatment with progress has been made in the treatment of Addison's disease."

That is fine except that as general practitioners we do not have available to us such non-commercial extracts and our patients have not the means to purchase them commercially.

Thorn and Firor, in their article, have the accompanying table showing the approximate cost of a year's medication.

At the price paid for cortical extract by our patient, 8 c.c. of the aqueous cortical extract per day would run to $1,170.00 for a year's treatment. That cost alone would seem to make Rowntree's method of treatment prohibitive in Addison's disease.

Preparation	Daily Requirement	Cost Per Year
Aqueous adrenal cortex extract	8 c.c.	$900.00
Synthetic compound in oil	2.6 mgs.	140.00
Pellets of synthetic compound	1.8 mgs.	98.00

Desoxycorticosterone acetate in oil does not exert its maximum effect until six to twelve hours following intramuscular injection. Therefore during the coma and the severe portion of the crisis it is necessary to supplement the synthetic hormone with intravenous and subcutaneous aqueous extract. For prolonged treatment one is forced to look elsewhere but before leaving the subject it should be reported that the natural extract has distinct uses in certain acute conditions such as toxemias of pregnancy, the acute toxemia of burns, in surgical shock and as pre- and postoperative treatment where stormy courses are expected or encountered.

A careful study of the cases reported by both the Baltimore and Cleveland groups indicates that use of the synthetic hormone is positively indicated in patients with Addison's disease who are unable to resume normal activity when treated with adequate quantities of sodium chloride and sodium citrate plus a diet low in potassium.

Thorn and Firor state:

"Desoxycorticosterone acetate is one of several crystalline substances isolated so far from adrenal cortical extracts. It is by no means certain that any one of the compounds thus far isolated represents the active form of the naturally occurring hormone. As tested by its potency in maintaining the life of adrenalectomized animals desoxycorticosterone is the most active of all the compounds thus far identified. . . . It is to date the only compound which has been synthesized and the only crystalline compound which can be obtained in quantities for clinical trial. It is evident that the quantity of supplementary sodium chloride administered to such patients must be carefully regulated during treatment with desoxycorticosterone acetate. Excessive quantities of the synthetic adrenal cortical principle and sodium chloride may result in the appearance of edema, hypertension and in some instances, signs of congestive heart failure. Occasionally the appearance of edema and excessive rise in blood pressure may necessitate a reduction in the dose of desoxycorticosterone acetate before the maximum therapeutic effect has been attained. Since the great increase in blood volume, the rise in blood pressure and the increased physical activity which follow the

institution of treatment with the synthetic compound rather suddenly place a considerable additional load on the cardiovascular system, it is advisable to restore most patients rather slowly to normal activity. The grave nature of the possible complications indicates the need for care in the institution of treatment and the necessity for continued medical supervision."

The same authors, concluding a report of continued and striking clinical improvement in twenty-one out of thirty cases treated by the pellet implantation method, state:

"Treatment with the synthetic adrenal cortical principle appears to be an efficacious form of specific therapy for patients with Addison's disease. The uniform potency and stability of the crystalline product permit more exact regulation of therapy. The relative inexpensiveness of treatment with desoxycorticosterone acetate will permit most patients to afford adequate therapy."

McCullagh and Ryan conclude their report on their six cases treated hypodermically with the following statement:

"Evidence is presented which indicates that desoxycorticosterone does not yield complete adrenal cortical replacement. In view of this, we feel that for the present, at least, it is in the best interest of the patient not to depend on desoxycorticosterone as therapy in Addison's disease to the exclusion of adrenal cortex extract in the presence of crisis or if some symptoms remain uncontrolled."

It is our opinion that marked progress has been made in adrenal therapy. The general practitioner can with advantage use both the extract and the synthetic hormone in certain acute toxemias and operative procedures. Where marked hypo-adrenia is noted by definite symptoms or where Addison's disease has appeared we now have at hand new therapeutic agents of proven efficacy and value. The practitioner may now feel that like diabetes, Addison's disease is losing its battle with medical progress and he should avail himself of both the natural and synthetic hormones and use them intelligently in conjunction with adequate sodium and reduced potassium intake in the treatment of all clinical conditions associated with hypo-adrenia.

Addenda

After the above report was written the patient continued on a high salt low potassium intake. The absorption of the hormone from the pellets did not seem to be quite sufficient to maintain her general well-being. However, irregular doses of 5 mgs. of Cortate intramuscularly made her feel fine and prevented any crisis.

Early in November, Schering again provided us with some pellets and we planted six, each weighing 150 mgs. in the anterior abdominal wall. These gave a theoretical absorption of .35 mgs. each or 2.10 mgs. per day for the six. The patient looked and felt well and except for occasional mild nausea was symptom-free. Her pigmentation was about as before and her blood pressure stayed about 140/80.

On January 5, 1941, she arose as usual, prepared breakfast and enjoyed it with her family. An hour later she went to her bed, lay down, told her husband she was nauseated and a moment later was dead.

At post mortem we recovered the pellets and checking their weight found that from them we had an absorption of 5 mgs. per day.

The post mortem examination of adrenal tissue showed that only 3 gms. remained instead of the normal 11 to 14 gms. Dr. George Berdez, pathologist, St. Mary's Hospital, Duluth, Minnesota, reported microscopic sections as follows:

"The cortical layers are completely atrophic and replaced by fibrous tissue in some area; in other areas, what is left of the cortex is densely and diffusely infiltrated with lymphocytes and shows also small groups of giant cells, some of them similar to those seen in tuberculous processes; there are, however, no tubercles and the arrangement of those giant cells would rather suggest that some of them are foreign body giant cells taking up debris of the breaking down tissues; other of those giant cells are the result of repeated nuclear division in reticulo-endothelial cells stimulated by the inflammatory process. Marked degenerated cells of the cortex, sometimes in small groups, sometimes isolated, can still be recognized in places. The cytoplasma of those cells stains diffusely red, is often finely granular. Frequently the nuclei do not stain. The medullary substance is also atropic and infiltrated with lymphocytes. In sections stained with scarlet red, small groups of cells of the cortex can still be recognized; some of those cells of the cortex are still loaded with granules staining red with scarlet red."

Our final conclusion in this case is that desoxycorticosterone acetate is of considerable value in preventing crises and in this case apparently gave our patient several months of life she would not have had without it. We believe more work will have to be done to determine the exact amount of daily absorption the individual obtains per 100 mgs. of implanted pellets. In addition we will have to develop some method of estimating more accurately the actual dosage required daily. The accurate required daily dosage of insulin can be established irrespective of the amount of destruction of the islands of Langerhans. In Addison's disease we apparently lack any criterion except the well-being of the patient.

INCISIONAL HERNIA AND ITS REPAIR*

A. E. BENJAMIN, M.D.
Minneapolis, Minnesota

ABDOMINAL operations are often performed in the easiest and quickest way possible to relieve the patient of the immediate trouble without due consideration of the ultimate results of the operation.

One of the complaints after a laparotomy may be an incisional hernia and, judging from the literature and records examined, I believe too many occur that could have been prevented had the operator taken into consideration all of the causative factors of incisional hernia.

The results of operations for these incisional hernias are none too satisfactory. These hernias usually occur in fleshy persons, especially women, in whom a hernia is not noticed by the patient at once inasmuch as most of them have been wearing a corset or abdominal support. The symptoms at first are vague and mild; the individual becomes used to the discomfort and the hernia develops so insidiously that the advice of a physician is not sought until the mass becomes so large that it is noticeable and unsightly, the suffering becomes severe, or obstruction of the bowel occurs.

The rate of occurrence of postoperative incisional hernias is difficult to determine, for usually only those that give trouble are seen and some others are observed in connection with more distressing maladies.

Some of these so-called postoperative hernias are simply a stretching or thinning out of the muscle because of the nerve injury at the primary operation.

Masson[5] reports 2.6 per cent of incisional hernias in all abdominal operations, or 14.66 per cent of all hernias. Mohorner[6] reports twenty-four incisional hernias in 112,686 cases admitted to the New Orleans Charity Hospital in 1937 and 1938. Hartzell and Winfield,[4] in a review of the literature, conclude that wound disruption occurs in about 1.5 per cent of cases and may be due to vitamin C deficiency. Cave,[1] in eleven years at Roosevelt Hospital, found 6.02 per cent of all hernias were incisional and 2.2 per cent incisional hernias occurring in 5,366 abdominal operations; and, in 162 drained appendices operated by McBurney's incision, twenty-one hernias developed.

Singleton and Blocker[8] state that hematoma and infection in 1,924 cases, reviewed by Jenkins, resulted in incisional hernia in 22 per cent. In reviewing 9,000 consecutive abdominal incisions, they report infection in sixty cases.

Infection of an abdominal wound is conceded by most surgeons as a potent causative factor in incisional hernias, especially if there is sloughing of the fascia. Abdominal operations for the drainage of abscess cavities, diseased gall bladders or ruptured appendices frequently are followed by incisional hernias.

I have observed that it is often possible to shorten the healing and convalescence periods in patients being drained for an abdominal abscess, by turning them over on the abdomen and allowing the pus to gravitate outward.

Rhodes and Hatterstein[7] conclude from experiments that tanned iodized catgut is the best suture material to use. Many surgeons prefer fine silk for the fascia, but I have been satisfied with chromic No. 1 or 00 with supplementary tension sutures.

When possible, the median incision is chosen in order to avoid injury to the blood and nerve supply: but, in potential hernia cases, the rectus may be pulled to one side and the peritoneum opened back of the muscle instead of in the center. However, care should be taken not to injure the deep epigastric vessel, for, as noted by Thos. C. Cullen,[2] "hemorrhage into and beneath the rectus muscle may seriously complicate the operation." I think this happens occasionally and results in an abscess weakening the abdominal wall. Sloan[9] believes that by using physiological incisions all incisional hernias can be eliminated except those caused by drains.

Incisions in the lateral abdominal wall are made in the line of the nerve supply when possible. If the main motor nerve to the muscle is injured there is apt to be insufficient tone and strength to these tissues and a weakened abdominal wall, with bulging or a real hernia occurring. The main blood vessels and nerve to the

*Read at the annual meeting of the Southern Minnesota Medical Association, Red Wing, September 23, 1940.

various layers of the abdomen should be conserved, if possible, in order to promote healing.

The peritoneum is often very thin or has a great deal of fat superimposed. A careless, hasty and imperfect closure of the peritoneum invites a postoperative hernia especially if the posterior sheath of the rectus muscle is not also carefully sewed.

Self-retaining wire retractors, as well as crushing forceps, may cause injury to the peritoneum and imperfect healing at these points. It has been my habit to avoid undue trauma or pressure to the peritoneum and to close the peritoneal membrane by suturing back and forth through its everted edges (Fig. 1-A). This gives a firm closure with a smooth inner surface and when a sufficient amount of tissue has been included there is little chance of a gap remaining in the peritoneal suture line. This is especially so when a second suture is run along the edges of the peritoneum and another along the fascial layer (Fig. 1-B). Dermal mattress sutures are also used, passed through the cut edges of the fascia, skin, and through rubber tubing and loosely tied. They relieve the strain on the other sutures and firmly hold the tissues so that oozing and consequent infection is less likely. Any exudate is evacuated by small drains extending through the skin to the fascia. The stay sutures may be left in for fourteen to twenty days. Subcuticular sutures for the fat layer are unnecessary when stay sutures are used.

There is no question but that minimizing intra-abdominal pressure lessens the possibility of hernia, and, therefore, nasal suction is always employed on the least indication of distention or vomiting, and the rectal tube for colonic gases. Additional essential vitamins are supplied, and transfusions are given when necessary. Food is given as tolerated.

The preliminary care of patients to be operated upon for incisional hernia is more essential than at the primary operation.

The patient should be sent to the hospital and kept there until the hernia is reduced, if possible. In order to determine more accurately the status of the case, a flat plate of the abdomen should be taken, and, in some instances, a barium enema and radiograph taken. Nasal suction will empty the stomach and intestines above any obstruction, and the colon should be emptied from below. In case of anemia, transfusions can be given. Heart complications should be studied, and pulmonary and laryngeal disturbances should be combatted.

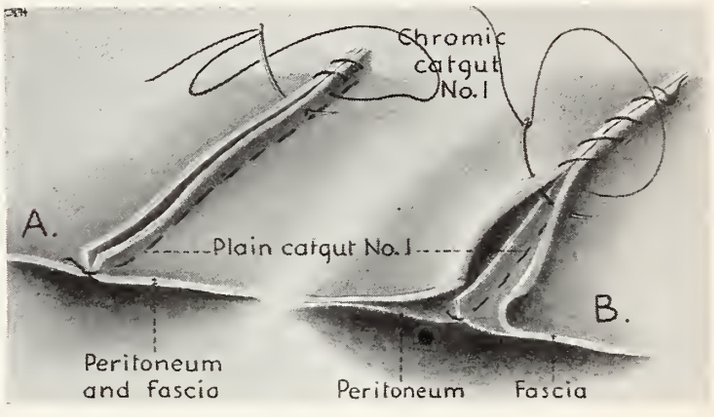

Fig. 1. Peritoneum everted, with suture lines.

Operation for Postoperative Hernia

A preliminary hypodermic of morphin and atrophin is given and local anesthetic used as a rule. The incision is transverse or perpendicular according to the size and location of the hernia, and should be sufficiently extensive to allow exploration for possible multiple hernias which are frequently present after a midline incision.

Where it is possible to separate the peritoneum from the fascia it is closed by an overlapping method with catgut. In cases with fairly good muscle structure, the sheaths are incised and apposed in two rows, making muscle approximation more perfect.

When the hernia is small, no doubt the transverse incision is best, and the flaps are overlapped as in the Mayo operation. This method overcomes the lateral pull of the abdominal muscles on the suture line, and should be chosen where possible.

Where the peritoneum is not easily separated from the fascia, the fascia and peritoneum and any thin muscle structure present are thoroughly separated from the fat and overlying skin. When the intestines are not distended with gas, these tissues may be overlapped laterally, the underlying peritoneal layer and fascial flap are stitched to the peritoneum on the opposite side with chromic catgut No. 1 (Fig. 2-A). Stay sutures are then passed through the skin from the side where overlapping occurs, through the upper flap and the fascia of the underlying flap and brought back through these tissues as a mattress suture. A row of these interrupted mattress su-

tures is placed along the abdominal wall. A second line of continuous sutures of chromic catgut, No. 0, doubled, fastens the edge of the upper flap to the fascia of the lower flap. This secures the two flaps firmly together and makes an impenetrable wall excepting, of course, in such cases where there is insufficient fascial tissue to make this operation possible. Under such circumstances a less extensive imbrication may be done and in some instances a pedicle flap of fascia is dissected from nearby tissue and turned in to complete this defect (Fig. 3). However, I have found few cases where this is necessary if the preliminary treatment has been carried on long enough to reduce the hernia and overcome some of the obesity and tension. In some instances it is necessary to put additional sutures along the flaps to secure them firmly.

The mattress sutures are tied over a long roll of gauze outside the skin which distributes the pressure, prevents the cutting in (Fig. 2-b) of sutures, gives a somewhat elastic tension upon the secured tissues, makes a broader surface of approximation of the structures, and lessens the possibility of hemorrhage, oozing, and infection. Each bleeding point is securely controlled and a few strands of catgut or small flat rubber drains are loosely placed through the skin line of incision to carry off any serous or bloody exudate that may occur beneath the skin. This system I employ in all other hernia operations. It gives excellent results.

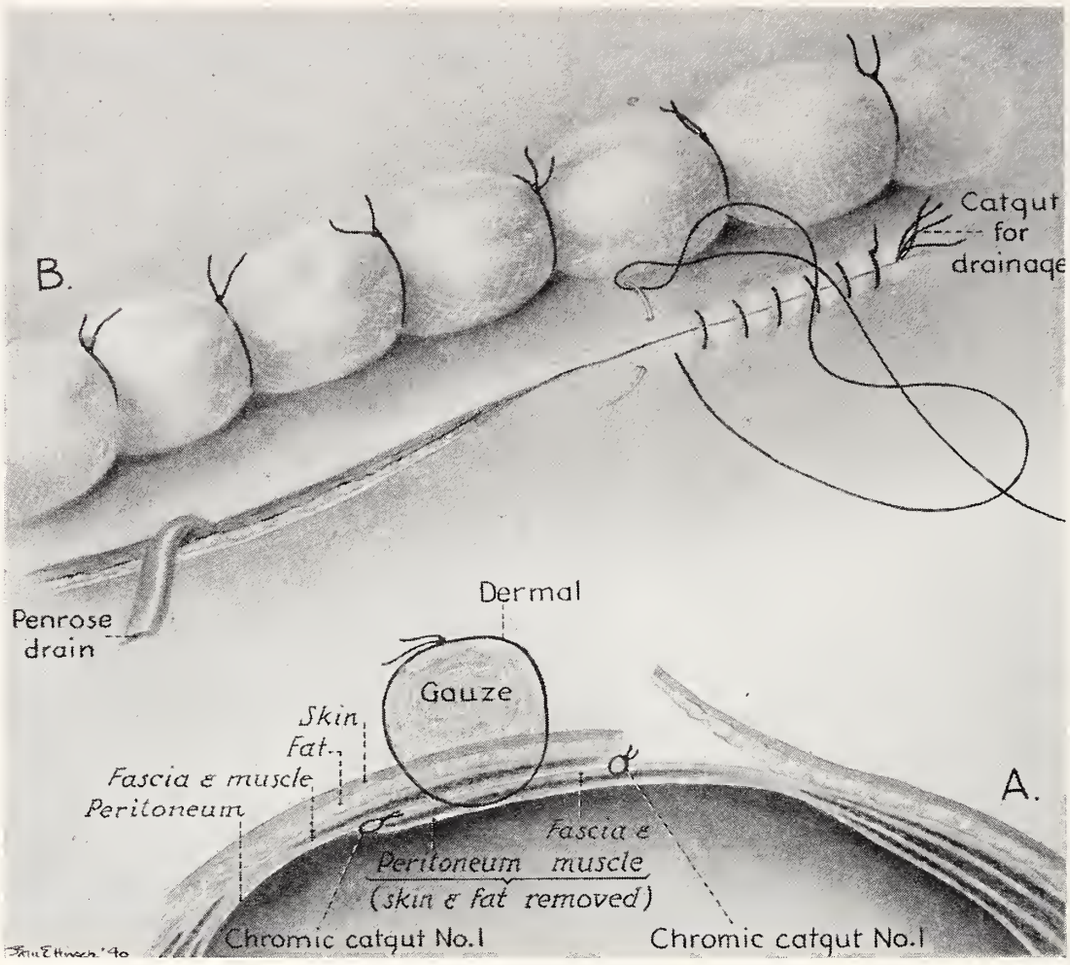

Fig. 2. Repair of postoperative hernia. Mattress sutures over roll of gauze on skin.

We have not used the Gallie[3] fascial strip to lace in and through the approximated structures, though we would not hesitate to do so if necessary. We have used the fascial flap. The extra time consumed and the added danger of infection makes this fascial strip operation more hazardous, however.

Smith and Masson[10] conclude that ventral hernias which they have not been able to repair previously can be repaired with sutures of fascia lata.

The lateral pull of the abdominal muscles may account for some recurrences. They should be immobilized as much as possible by abdominal adhesive strips and a binder directly following the operation. It is well to apply these strips after the wound is healed and left supporting

the abdomen for several weeks, but an abdominal support should also be properly fitted and worn for months thereafter. Tone and strength of the abdominal muscles should be restored by systematic daily exercises.

The rate of recurrences is variously estimated, but averages about 36 per cent. This percentage can and should be reduced.

The following is a summary of the records of a series of seventy-seven cases of incisional hernias studied at the University of Minnesota Hospital.

The ages ranged between twenty-two and seventy-eight years; forty-three were females and thirty-four males.

Forty-six were operated upon for repair of the incisional hernia; thirty-one were not. Of the forty-six patients operated upon, twenty-four were by the lateral overlap method, three by the Mayo method, and six by the direct method.

Of the forty-six patients operated upon, twenty-seven had complications, namely, gallbladder, appendicitis, pelvic tumors, or diabetes, heart or kidney trouble. One patient died in this group, a mortality rate of 2.9 per cent.

Of the thirty-one not operated, most had complications more serious than the hernia, so operation was deferred.

Of the forty-six operations, the immediate results were satisfactory in thirty. The ultimate results we were not able to determine from the chart records as many did not return for a checkup. In 9 cases (20 per cent), the results were poor.

The primary operations, followed by the hernias, were: nine appendectomies with drainage, three for gallbladder, and the others were for pelvic tumors, tubal trouble, etc.

In a similar summary of 125 cases at Minneapolis General Hospital, we found:

The ages ranged from ten to eighty-two years. There were sixty females and sixty-five males.

Fifty-three patients were operated upon for repair of the hernia. Seventy-two were not operated upon, because of other serious or more important disorders.

Of the fifty-three operations, thirty-two were by the overlapping lateral method, one by the Mayo method, twelve by direct approximation, one by incision of recti sheaths, one by using a Gallie fascial strip, and three a fascial flap.

Of the fifty-three patients operated upon, one died, a mortality of 1.8 per cent. All the other patients operated upon were improved when discharged but the percentage of recurrences is difficult to estimate as few returned for a checkup.

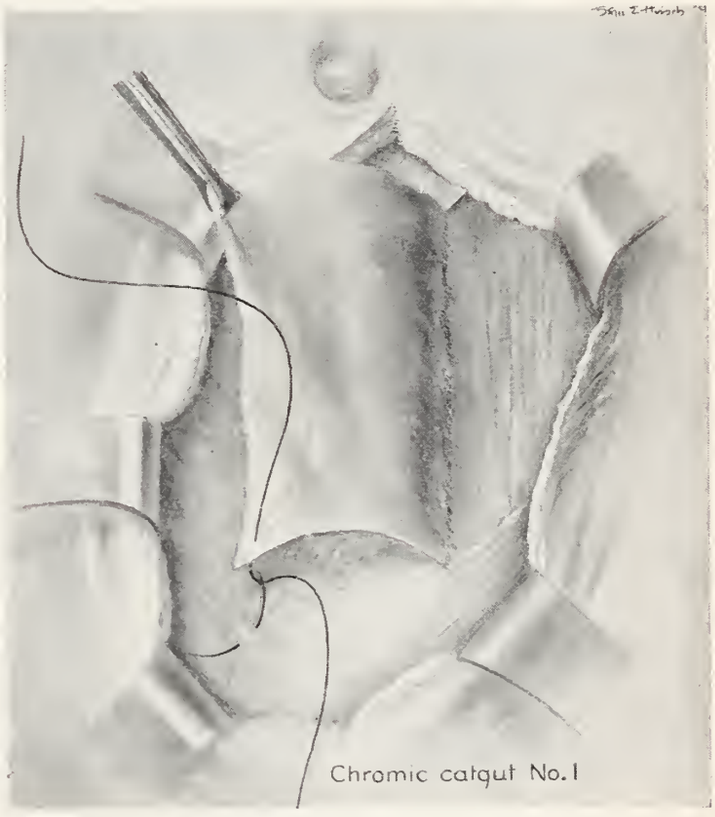

Fig. 3. Fascial flap repair of postoperative hernia.

The primary operations which were followed by hernia were: twenty-seven appendectomies (21.6 per cent); fourteen gall-bladder operations (11.2 per cent); and the others were hysterectomies, tumors, ulcers, et cetera.

In a series of fifty-five private cases of postoperative abdominal incisional hernias, there were forty females and fifteen males. Thirty-one females were operated upon for repair of the hernia; nine had either small non-disturbing hernias or associated diseases more troublesome than the hernia. In those operated upon, the results were good, excepting two who each had a small recurrence. These were in obese women who had inadequate support at first, but have little trouble with the hernia now.

Of the fifteen males, all were operated upon except two, who have very little trouble with the hernia. The results were good in all those operated upon and there were no recurrences in this group.

Of the forty-four patients operated upon, the cause of the hernias in twenty-one cases was acute appendicitis with prolonged drainage, where

the patients were not turned over on the abdomen after operation. In nine instances the previous operation was for gall-bladder disease with drainage. In twelve cases a low median incision had previously been made for operations on the pelvic organs in rather obese women and drains employed in three cases. One of these patients weighed three hundred and thirty pounds. There was inadequate support in most of these cases following the primary operation. The remaining hernias followed operations for carcinoma of the colon.

The direct apposition of structures with imbrication of the external fascia was done in seven cases. The Mayo operation was performed in three cases. In all others there was an overlapping of the opposing structures in layers when possible, or when inseparable as a single flap, supplemented by a contiguous fascial flap in two cases. These overlapped structures were united with chromic catgut No. 1 or 0, doubled, and stay sutures tied over rolls of gauze or rubber tubing. Drainage through the skin was secured by small catgut strands or small flat rubber drains.

Whenever possible, the hernial sac was carefully dissected to within the abdomen and was secured to the inner abdominal wall opposite firm abdominal wall tissue where feasible.

In this series of private patients operated upon for repair of the hernia, there was a recurrence of 4.6 per cent and no mortality, but in all of them we were able to prepare the patient for the operation, except in two cases where there was an obstruction so severe that an immediate operation was performed. Some of these patients were advanced in years and had little resistance; others were operated upon for some associated trouble as well.

Two died of cancer of the colon a year later. Four have thin walls and some pain and might have a recurrence if no support were worn.

We may attribute the success of this work to: (1) the time permitted for preparation of the patient for an operation, (2) the use of local anesthesia in most cases; (3) the employment of nasal suction when necessary; and (4) the fixation of tissues by means of the stay sutures tied over gauze rolls or rubber tubing which makes a broader apposition, lessens bleeding, and prevents cutting of sutures.

Conclusions

1. The incidence of incisional hernias following abdominal operations is greater than it should be, and is more than most records show.

2. Surgeons should conserve nerve and blood supply and give more thought to the possibility of hernia following a primary laparotomy in order to prevent such an occurrence.

3. Essential vitamins and blood transfusions when indicated should be supplied at the primary operation.

4. The preparatory treatment for an incisional hernia operation is very important.

5. The general condition of the patient should be satisfactory and, except in emergency cases, the hernia should be reduced before operation.

6. The incision for a cure of incisional hernia should be adequate to permit the correction of any obstruction to the bowel, and proper identification of the tissues and all openings.

7. A small single hernia may be repaired by the Mayo method, but a large single or multiple hernia should be corrected by lateral overlapping of tissue with the addition of fascial flap or Gallie's fascial strip where necessary.

8. The mattress Dermol suture has proven most satisfactory in holding the supportive flaps together, when tied over rolls of gauze or rubber tubing on the skin and should be left in place for two to three weeks.

9. Very small rubber or catgut strands give ample drainage of subcutaneous areas.

10. The nasal suction tube should be used in most of these cases for two to four days.

11. Snug adhesive bands should be applied directly following the operation, and a well-fitting abdominal support worn constantly for several months after these operations.

DERMATITIS MEDICAMENTOSA
A Teaching Summary*

LOUIS A. BRUNSTING, M.D.
Rochester, Minnesota

BY "dermatitis medicamentosa" is meant an eruption which occurs in a sensitized individual following the absorption and dissemination of drugs. The term "drugs" includes medicaments in general, simple or complex materials which act through the whole molecule or a particular split product. The portal of entry may be the skin, by means of contact or inunction (iodine, mercurials, procaine, quinine), the gastro-intestinal tract, by means of the mouth or rectum (phenolphthalein, barbiturate derivatives, atropine), the deeper tissues, by means of parenteral injection (salicylates, gold salts, arsphenamine), or rarely, the respiratory system, by means of inhalation (ipecac, belladonna, pyrethrum). Drug eruptions are primarily allergic in nature, but not altogether so. Although the skin and mucous membranes are the chief sites of attack, untoward reactions may appear in other tissues, such as the liver, the hematopoietic system, or the vascular network of the gastro-intestinal tract, the genito-urinary tract or the brain.

So that the nature of drug eruptions and their allergic features may be understood, it may be well to emphasize herein a few distinctive points in summary.

The Patient

Concerning the rôle of the patient, it may be said that:

1. Drug eruptions are relatively rare.

2. Such eruptions are acquired reactions of idiosyncrasy occurring in certain predisposed individuals.

3. The mechanism of sensitization of such individuals is little known. Experimentally, the skin of man and animals can be sensitized to certain chemicals (mercury, orthoform, salicylates, arsphenamine, formaldehyde, extract of primulin or rhus and others).

4. Sensitivity of the individual is achieved after a variable period of incubation. This period may range in duration from days to years, depending on the nature of the drug, the dose, the frequency of exposure, and most of all, the degree of susceptibility of the individual. A tolerance of years may be interrupted suddenly by the occurrence of symptoms of sensitivity.

5. Once acquired, the state of sensitivity is usually permanent, although the clinical reactions may vary in character and intensity from time to time.

6. No circulating reagins can be demonstrated by passive transfer.

The Drug

Concerning the rôle of the drug in this condition, it may be said that:

1. No drug is free from sensitizing properties, although there is considerable variation among drugs in this respect. For example, some of the well-known drugs may be classed as in Table I.

2. Drug eruptions are distinct from the pharmacologic or toxicologic effects of drugs. Cumulative effects of drugs are not observed (except perhaps in the case of bromoderma and argyria). Graded doses of drugs do not precipitate reactions of equivalent degrees. Drug eruptions have no counterpart which can be measured on animals in the experimental laboratory.

3. It is commonly thought that the dose needed to precipitate a drug eruption must be higher than the usual therapeutic dose, but this is not so. If an individual is sensitive to a particular drug, even a trace of that drug may be sufficient to provoke the eruption.

4. Reactions of sensitivity may be limited specifically to a group of similar drugs, to a single drug, or to a particular chemical fraction of a drug.

5. The degree of chemical purity of a drug is not a factor in the production of drug eruptions.

6. Sensitizing drugs are often concealed in proprietary products (quinine in certain anodynes, phenolphthalein in cathartic agents or bile salts, acetanilid in certain commercial preparations for relief of headache and other pains).

---

*From the Section on Dermatology and Syphilology, The Mayo Clinic, Rochester, Minnesota. Read before Center for Continuation Study, University of Minnesota, Minneapolis, Minnesota, July 30, 1940.

The Reaction

Concerning the reaction, it may be said that:

1. Drug eruptions appear in unusual patterns, the nature of which is influenced by the type of drug that is concerned, the reactive capacity of the individual and the quality of his skin.

2. Reactions are usually unexpected, with an abrupt onset.

3. Constitutional symptoms, as a rule, are mild. However, in severe reactions fever, malaise, bleeding and death may occur.

4. The character of the eruption is sometimes distinctive for certain drugs (bromide, iodide, phenolphthalein); more often it is not. These eruptions must be distinguished from the contagious exanthems and from such common diseases of the skin as pityriasis rosea, secondary syphilis, urticaria and eczema. In the condition under discussion there is such a wide diversity of cutaneous manifestations that a proper dermatologic background is required if the physician is to arrive at the correct diagnosis.

5. Sensitization may be epidermal, in which case the reaction will be eczematous in nature, as in contact dermatitis as caused by mercurials, procaine hydrochloride, quinine, solutions of formaldehyde and others.

6. Sensitization may occur in the cutis (the vascular network ?), in which case a symmetrical eruption will appear, chiefly urticarial in nature, but presenting at times all the forms of elemental lesions of the skin, including purpura. Often combinations of the above occur on various occasions.

7. The mucous membranes of the mouth, genitalia and perianal regions are frequently involved. Some eruptions referable to drugs, such as phenolphthalein, show a predilection for mucocutaneous junctions.

8. A not uncommon form of reaction is the "fixed drug eruption" in which there is focal sensitization of the vascular network underlying a circumscribed site in the skin. Multiple sites may be so affected, and these sites may include the mucous surfaces. On occasions, when the offending drug is brought by the circulation to these particular regions, a characteristic flare results with spreading erythema, edema, pruritus and finally pigmentation. Bullæ sometimes form. Certain drugs possess the power of producing reactions in the form of fixed eruptions. The most common of these are phenolphthalein, arsphenamine, antipyrine, aminopyrine, acetophenetidin and barbiturate drugs.

9. The diagnostic value of cutaneous tests (performed by the patch technic), in proving the

nature of the offending agent, is limited to a few conditions, chiefly those in which the drug produces an eczematous reaction. Drugs concerned are atropine, arsphenamine(?), chloral hydrate, dyes, solutions of formaldehyde, iodine, iodoform, mercury, quinine, turpentine and the group of local anesthetic agents.

10. Common cutaneous reactions to some familiar drugs are presented in Table II, with the diseases of the skin which they simulate.

Comment

Inasmuch as drug eruptions possess such unusual qualities, diagnosis often must be made by means of exclusion. Dermatologists have a convenient rule of thumb which holds that an eruption, which appears unexpectedly, and in an odd design which does not fit the pattern of the familiar clinical entities, is either a self-induced factitious affair or a reaction of the patient's sensitivity to medication.

The physician may be too timid or too indirect in questioning the patient to permit him to arrive at the correct diagnosis. When the eruption appears on the skin and drugs are suspected to be causative factors, it is not sufficient to abide by the patient's denial of usage of drugs. Many persons consider the term "drugs" to apply only to habit-forming narcotic agents. Moreover, many sensitizing drugs masquerade as harmless proprietary preparations under the influence of forceful publicity. Consider, for example, arsenic and iodides in tonics, bromides in "nerve medicines" and in remedies for headache and colds, phenolphthalein in cathartic agents, bile salts, "liver pills" and medicated gum. Unless these sources of supply of offending materials are carefully ruled out by direct inquiry of the patient, in language he can understand, the history will avail nothing. In some instances, it would be well to disregard a seemingly irrelevant history when the diagnosis seems objectively to be self-evident, and occasionally, to obtain definite proof, it may be necessary to provoke another attack by giving the patient small amounts of the suspected materials. This should not be done in a casual manner to satisfy intellectual curiosity, for embarrassing reactions and perhaps dangerous consequences may result from such a procedure if it is employed without caution.

Appreciation of the significance of drug eruptions and other reactions to drugs is important to the physician who uses arsphenamine in the treatment of syphilis. Exfoliative dermatitis would be a rare complication of therapy for syphilis if the earliest evidences of the patient's intolerance were understood and the warnings heeded. In such cases of sensitiveness, as well as in others in which drug eruptions have been noted, some conspicuous notification should be placed in the clinical records and indelibly impressed on the mind of the patient. Too frequently such a patient feels, and perhaps rightly, that proper precaution had not been taken in the selection of drugs or in the matter of dosage for him, because he has no understanding of idiosyncrasy. The wise physician will remember always that certain individuals possess the capacity to react to medications in a peculiar way.

FRACTURES OF THE DISTAL HALF OF THE TIBIA AND FIBULA*

E. H. JUERS, M.D.
Red Wing, Minnesota

THERE is no doubt that fractures of the lower half of the tibia have always and will always present a special therapeutic problem. This is especially true if these fractures are spiral or comminuted in nature.

A system for the treatment of fractures of the lower half of the tibia and fibula is to be presented: (1) because it has given uniformly good results; and (2) because it is simple, and it is easy to carry out.

Transverse fractures need little discussion except to point out that the fragments should be restored to complete or nearly complete anatomical position. A simple technicality frequently overlooked in the process of reducing the fracture is failure to compare the injured extremity with the normal one. Special attention should be given to the bowing of the tibia, which normally

may or may not be present. After reduction the extremity should be immobilized in a plaster-of-Paris cast. This cast should extend from the toes to the groin. The knee should be held in a position of from thirty to forty degrees flexion. This will prevent rotation of the fragments between the knee and the ankle. The foot is placed at right angles to the leg and in slight inversion. A mistake commonly made is failure to flex the knee sufficiently and failure to extend the cast to the groin. Many times a cast is seen which extends only six or eight inches above the knee. Immobilization of this type does not prevent rotation at the fracture site and frequently results in non-union.

Spiral fractures present quite a different problem in that reduction cannot be maintained in quite such an easy manner as in the case of transverse fractures. Therefore some other form of immobilization has to be used in order to maintain reduction. For these fractures the following proceedure has been carried out. First a

Steinman pin is inserted through the os calcis and the necessary dressing applied. With the aid of two or more assistants or a fracture table, the leg is placed in correct alignment and the knee is flexed to about sixty degrees. A plaster-of-Paris cast is then applied, holding the leg in this position. The foot is not included in the cast other than extension of a plaster splint over the dorsum of the foot. This extension of plaster goes beyond the toes to prevent the bed clothes from bearing down on the toes and it is also used later to help prevent a foot drop. An ordinary gauze bandage is used to support the foot. A stirrup (Fig. 1) containing a windlass is then incorporated in the cast. This stirrup is placed in the position of the lateral alignment of the tibia. Two strips of flexible material are then fastened to the Steinman pin. The anterior-posterior alignment is then completed and in this position the strips for traction are placed in the windlass and traction is made. Apposition and alignment are spontaneous. The leg muscles are well relaxed because of flexion of the knee. The thigh serves to give counter traction. Sufficient traction is made to obtain correct length. This is maintained until there is evidence of callus formation. The Steinman pin and the traction are then removed and a new cast is applied extending from the groin to the toes. The knee is held at about thirty degrees of flexion. When sufficient callus has formed to assure union, a short leg cast is applied and changed when necessary for the remainder of the period of immobilization. During the last few weeks of immobilization a walking iron incorporated in the cast may be used to good advantage.

In one case, as illustrated, the patient sustained a spiral fracture of the tibia and fibula as is shown in Figure 2. There is considerable overriding of the fragments as well as a marked amount of separation laterally. Figure 3 shows the result five months after injury. This patient was able to bear full weight without the aid of crutches six months after the accident.

This method of immobilization has worked equally well in cases of severely comminuted fractures of the lower half of the leg. The accompanying illustrations represent a case of a severly comminuted fracture of the tibia and fibula, with extension of the fracture into the ankle joint. Figure 4 shows the original fracture. Figure 5 illustrates a lateral view after reduction and Figure 6 shows the anterior-posterior view after reduction. The last illustration (Fig. 7) shows the end-result. This radiograph was taken eight months after the accident. There was no permanent disability.

Conclusions

1. The abnormal leg should always be compared with the normal.
2. Immobilization for fractures of the tibia should be obtained by a plaster-of-Paris cast applied from foot to groin.
3. The optimal positions in which to immobilize the knee and ankle in case of fractures of the tibia and fibula is discussed.
4. A simple, expedient, and relatively mobile method for the treatment of the difficult fractures of the lower half of the tibia and fibula is described.

TUBERCULOSIS MORTALITY AMONG WOMEN

As long as reliable mortality statistics for tuberculosis have been known, young women have always been more prone to die of tuberculosis than have their young brothers or older sisters. While the general death rate from tuberculosis has steadily fallen, the death rate among young women has also decreased, but at a slower rate. The fact remains that tuberculosis is prevalent enough, particularly among young women to warrant, in the opinion of many authorities, a tuberculin test on all pregnant women. Treatment of tuberculosis has advanced so rapidly in recent years, that with early recognition of the condition in pregnancy, it is possible in many cases to bring the baby through safely with no danger to the mother.—National Council for Mothers and Babies.

DIAGNOSIS AND TREATMENT OF CONDITIONS ASSOCIATED WITH VARICOSE VEINS*

FREDERICK L. SMITH, M.D.
Rochester, Minn.

IN presenting this subject I am particularly interested in laying special emphasis on conditions encountered with varicose veins at the time of examination and in making suggestions regarding their treatment rather than the treatment of the varicose veins and complications resulting therefrom. During the last ten years much has been written about the diagnosis and treatment of varicose veins. Whether injection alone, single ligation at the juncture of the saphenofemoral veins, and multiple incisions to care for the incompetent communications of the deep system or combined surgical and injection treatment is the procedure of choice remains for the future to decide. Personal experience of many engaged in the work eventually will eliminate the procedures which results have proved inadequate.

Patients presenting themselves for examination of the extremities often have changes of the skin which are either directly attributable to incompetency of the veins or secondarily present as the result of local pathologic conditions. The contributing factors to the latter come from intercurrent complications arising either as a result of the varicosities or from extrinsic factors such as excessive weight, lymphatic occlusion, thrombophlebitis in varying degrees, traumatism and local infections. Among the more frequent conditions which I would like to discuss are changes in the skin varying from small discrete patches of eczema to diffuse involvement of the leg and ankle with occasional extension along a varicose vein onto the thigh. Patients afflicted with localized dermatitis usually give a history of varicose veins of many years' duration with local changes taking place at a subsequent date. Occasionally a patient will be seen who does not have any perceptible edema and only a small incompetent varix leading into the region, but who complains of itching. If the itching is of any duration, a thickened pigmented skin results and in turn a typical neurodermite develops.

Stasis Dermatitis

In the early stages of stasis dermatitis generalized edema of the skin with scaling is observed on the lower third of the extremity and the ankle. This gradually ascends as involvement becomes more marked. Essential characteristics are edema, crusting, weeping and marked itching.

Obliteration of the existing varices in the less extensive cases usually relieves the local itching. Application of 3 per cent ichthyol in zinc oxide ointment with a sponge pad or elastoplast bandage at intervals of five to ten days usually suffices. When a diffuse eczematous condition exists, the patient should be hospitalized, the leg elevated at least 30 degrees and cold applications of 0.5 per cent solution of aluminum subacetate should be used. This procedure not only relieves the excessive irritation of the skin but the edema of the leg. Sclerosing treatment of the incompetent vein is then begun and supportive bandages should be worn during and following the course of treatment for at least several weeks or months depending on the individual circumstance.

The presence of eczema and changes in the skin often obscure the basic cause. Incompetent veins are not always in evidence on the extremity or in the thigh. In many instances the great saphenous veins cannot be seen in the thigh but by manual palpation incompetence may be discerned which is indicative of a reversed flow of blood column and stasis with dermatitis ensues.

Brawny Infiltration

When local superficial lymphangitis of varying degrees has occurred, the inflammatory process results in destruction of the superficial lymphatics, and subcutaneous atrophy with discoloration and fibrosis occurs.

If extensive lymphangitis or cellulitis has appeared, annular constriction with lymphatic edema may be found below the involved region. Regions of brawny infiltration which are associated with impairment of nutrition and lowered resistance are fertile fields for ulceration and

*From the Section on Postoperative Care, The Mayo Clinic, Rochester, Minnesota. Read before the Meeting of the Upper Mississippi Medical Society, Cass Lake, Minnesota, August 10, 1940.

infection. Protective measures should be employed to prevent traumatism and if edema is more or less extensive, pressure pads of gauze or rubber sponge should be snugly bound to the leg by a good fabric bandage to facilitate circulation to the part.

Ulcers

Ulcers of the extremities occur from various causes and are often confused with varicose ulcers in the presence of varicose veins. Ulcers of fungus origin, such as blastomycosis, may be mistaken for ulcerous lesions of medicinal origin such as those caused by bromides or iodides. The treatment consists of administration of iodides, roentgen therapy and local treatment with iodine, electrocoagulation, carbon dioxide and deep freezing peroxide sprays.

Ulcers arising from local infection, such as insect bites or local trauma, ordinarily respond to local treatment and resolve in a relatively short time. Ulcers arising from medicinal basis respond by elimination of the drug. When they are infected secondarily, they may exist for a long period and may be mistaken for true varicose ulcers.

In cases of malignant ulcer in the presence of varicose veins with or without edema, there is usually a history of a small ulcer at the beginning and of gradual extension over a period of a few months to several years. The border of the ulcer appears blanched in contradistinction to varicose ulcers in which the edges are irregular and thick, and are usually discolored. In such cases biopsy should be performed and if the ulcer is malignant, surgical or radiotherapy or both should be instituted.

Ulcers Resulting from Arteriovenous Fistula.—"Hot ulcers," a term used to distinguish the arteriovenous ulcer from the ordinary varicose ulcer, are characterized by marked increase of local heat in the presence of edema and beginning atrophy. The arterial supply to the part is short-circuited and if many fistulous arteriovenous communications exist, ulceration occurs at the dependent part. Such ulcers are painful regardless of the type of treatment employed.

Elevation of the extremity does not relieve the condition as it does with true varicose ulcers and dependent positions intensify the pain. My experience has been that a bandage of heavy material and a level position seem to afford the best relief.

Syphilitic Ulcers.—Blood tests for syphilis reveal the origin of these ulcers. In addition the syphilitic ulcer has certain changes in the border that are suggestive of the etiologic factor although they are not clearly diagnostic objectively. The border of the ulcer is arciform and markedly indurated. Usually only a single ulcer is present. Specific treatment is consequently indicated.

Thrombophlebitis

Much has been written in textbooks and original papers regarding the hazards of treatment of varicose veins in the presence of thrombophlebitis. In a series of 491 cases in which treatment for varicose veins was given, 12.5 per cent of the patients attributed the cause to phlebitis. My first experience in treating varicose veins in the presence of acute thrombophlebitis occurred in 1931. The patient had rather mild, acute phlebitis of the left great saphenous vein after subtotal abdominal hysterectomy. Examination revealed two discrete regions of phlebitis along the course of the vein on the nineteenth or twentieth day after operation. The patient was not experiencing any systemic symptoms. I injected a minimal dose of sclerosing fluid into the vein in the middle and upper thirds above the sites of involvement. Undue symptoms were not noticed in the course of treatment. Since that time at the clinic we have disregarded phlebitis as a serious contraindication to the treatment of varicose veins with two exceptions: (1) when a systemic reaction such as fever, marked local redness and swelling are present, we wait until the activity has subsided and resolution is fairly well advanced; and (2) when swelling of the extremity and enlarged compensatory veins are noted, the deep circulation is always tested for adequate return of the venous flow. If no pain occurs after the patient has worn an Esmarch rubber bandage snugly applied from the toes to the knee for twenty minutes or so, the occlusion which is manifested by the dilatation of the collateral veins, is not sufficient to render treatment of the varices inadvisable.

Migratory phlebitis[2] may be differentiated from the usual thrombophlebitis for it varies both in its incipiency and recurrent tendencies. The

patients will present a small, tender, superficial patch which runs parallel to the vein with some perivascular lymphatic involvement. As the name suggests, new lesions appear frequently and the old ones may recur and subside. If it is extensive, slight rise in temperature may occur. In this condition the wall of the vein seems to be affected rather than the lumen and on palpation the vein seems to be of a cord-like nature. The lesions appear in segments of the vein and because of this tendency an infectious origin is suggested. Superficial veins usually are involved. The recurrence is of a migratory nature and a continuous regimen of treatment for from a few weeks to months may be necessary. This regimen consists of hospitalization, elevation of the extremity and application similar to those used in the treatment of ordinary thrombophlebitis.

Miscellaneous Conditions

Arteriovenous fistula in the presence of varicose veins is not always easy to diagnose, if there are no local changes in the skeletal structure such as enlargement of the bones or lengthening of the extremity. Bruit and thrill which are given in textbooks as positive signs of arteriovenous fistula, are not detectable in the majority of cases of congenital arteriovenous fistula. If varices fail to sclerose after successive doses of a number of sclerosing agents, arteriovenous fistula should be suspected. Study of the oxygen in the blood will clarify the diagnosis. If the oxygen content of the venous blood in the varix is more than 65 or 70 per cent, arteriovenous fistula is probably present.

Muscle sheath hernias appear as single or multiple protrusions on the lateral and posterior surfaces of the lower extremities. They are easily distinguished from varicose veins by having the patient stand on the toes for extension and then on the heels for flexion. In each instance the protrusion disappears if a muscle sheath hernia is present. If the protrusion still persists, varicose veins are probably a factor.

Baker's cysts of the popliteal space occasionally are found in the course of examination of varicosities. The fact that the lateral saphenous veins and the plaque of dilated veins from the great saphenous veins may be in the immediate region, may confuse the examiner and the cyst may be considered a part of the varicose involvement. Ruling out the presence of a cyst in the popliteal space will prevent complications. Such cysts are filled with synovial fluid and for that reason an accidental injection into the cyst might cause serious complications. To differentiate a cyst from varicose veins the patient should be placed in the prone position and the leg flexed to reduce the volume of fluid in the varices. If there is a marked prominence at this time, the chances are that a cyst is present. If this simple test is not conclusive a hypodermic needle should be inserted in the prominence and fluid withdrawn. If synovial fluid is obtained, the diagnosis is clinched.

Tuberculous lesions and erythema induratum are rarely encountered in varicose vein therapy. However, the possibility of such lesions should be kept in mind when indurated subcutaneous nodules are present which are tender to the touch. In such cases after several weeks or possibly months redness and occasional fluctuation with final necrotic surface may occur. These lesions are found for the most part on the posterior surface of the legs. Treatment consists of supportive bandaging, local topical applications of an antiseptic nature, tuberculin regimen and general systemic measures to increase body resistance.

Erythema nodosum is manifested by tender nodular lesions which may appear red and gradually fade to a purplish hue when receding. They usually are situated on the anterior surface of the legs. The trunk and arms are occasionally involved. Clinical examination usually reveals fever and the history of arthritis although in the persistent type of the disease, tuberculosis is a frequent cause. As for treatment, the administration of salicylates, local astringents, rest, and so forth are the usual procedure.

Pyoderma gangrenosum[1] is characterized by discrete pustules which enlarge and necrose. If there are many in a small region, they coalesce in a crusting ulcer. The edges may be undermined and the contour is usually oval. When such an ulcer is found there is likelihood of its being secondary to some internal systemic infection. It has been suggested that ulcerative colitis may be a factor. Hemolytic streptococcus and staphylococcus have been isolated from the ulcer. Treatment consists of endeavoring to find the invader and then to treat it. Various local treatments have been tried with some degree of suc-

cess; these consist of specific serum and topical dressings, heliotherapy, and so forth.

Summary

I have attempted to call attention to possible associated conditions in the presence of varicose veins and to discuss their treatment not in detail but sufficiently to put the physician on guard against committing undue errors in management. Whenever systemic involvement is associated with lesions of the extremities, treatment for varicose conditions should be deferred.

METASTASIZING ARGENTAFFINE TUMOR OF THE CECUM IN A CASE OF MULTIPLE COLONIC MALIGNANCIES*

CHARLES W. MAYO, M.D., and WILLIAM D. WILSON, M.D.
Rochester, Minnesota

ALTHOUGH there are a great many reports in the literature concerning cases of carcinoid tumors of the appendix, tumors of this type occurring elsewhere in the gastro-intestinal tract are relatively rare. Evidence of extension from the site of origin of these tumors is even less commonly encountered. Wyatt, in 1938, reported a case of "multicentric carcinoid" of the cecum in which the tumor had metastasized to the liver. Including the case of Wyatt, only nine cases of this type of tumor of the large bowel have been reported, of which only three have been found to have either local or distant metastasis. Of the cases of carcinoid tumors of the appendix, only five have been found to have extended beyond the organ itself, although many such tumors have been reported on in the literature. Only thirty-six cases of this type of tumor of the small intestine in which extension was found on examination have been reported. Because of the relative rarity of extension in this type of lesion, particularly when the lesion is situated in the large bowel, it was felt that the following case would be of interest.

Report of Case

The patient, a white woman fifty-five years old, was admitted to The Mayo Clinic on March 11, 1939, complaining of pain in the left lower quadrant of the abdomen of about three and a half years' duration. On two or three occasions she had passed bright blood per rectum. Associated constipation of considerable degree was present, so that it had been necessary for her to use enemas almost daily. Physical examination revealed essentially normal observations. Proctoscopic examination showed that a polypoid carcinoma was situated 10 cm. above the dentate margin; the lesion involved the left and posterior walls of the rectum. This lesion extended for 16 cm. proximal to this point. Biopsy revealed the tumor to be an adenocarcinoma, grade 1. Because of the presence of this lesion in the rectum, roentgenologic examination of the colon was not made before operation, since it was desired to prevent possible obstruction which might have resulted from the retention of barium proximal to the rectal growth had such an examination been attempted. The plan was to perform a one-stage combined abdominoperineal resection.

On March 13, 1939, a primary left rectus incision was made. Examination of the rectosigmoid revealed a neoplasm as described at the time of proctoscopic examination; it was attached to the lower portion of the uterus as well as to both fallopian tubes and ovaries. The liver and gall bladder were normal to palpation. Examination of the cecum revealed a small mass, about the size of a golf ball, situated in this region close to the ileocecal valve, and there were palpable glands in the right part of the mesocolon. It was felt that this lesion unquestionably was another carcinoma. Accordingly, one-stage resection of the right portion of the colon was performed and an end-to-side ileotransverse colonic stoma was made. Single barrel colostomy, after the method of Lahey, also was performed, so that in the future the second part of two-stage abdominoperineal resection could be accomplished.

The patient's convalescence was excellent following this procedure, and on April 13, she underwent the second part of the combined abdominoperineal resection. The inflammatory reaction around the rectal lesion was much less this time than it had been previously, a fact

*From the Division of Surgery (Mayo), The Mayo Clinic, Rochester, Minnesota, and The Mayo Foundation (Wilson).

which enabled the surgeon to strip the uterus and right fallopian tube free without any difficulty. It was necessary, however, also to remove the left fallopian tube.

Progress of the patient after performance of this procedure was satisfactory and she left our care on May 11 in excellent condition, having gained several pounds since undergoing her last operative procedure. She was seen again February 20, 1940, at which time her general condition was excellent and there was no evidence of any malignancy.

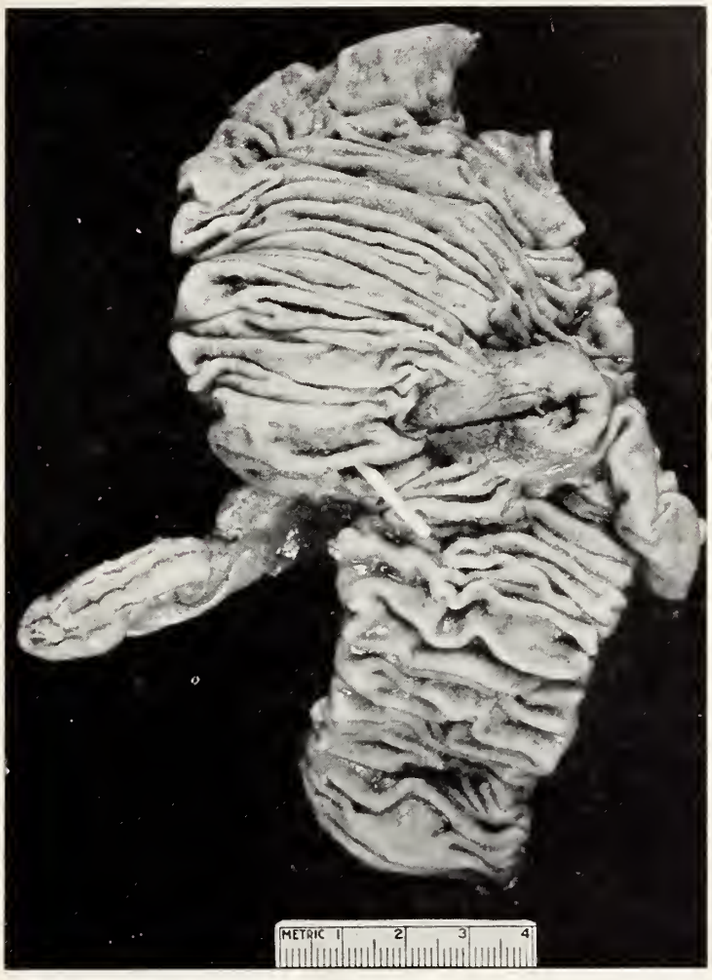

Fig. 1. Grade 2 adenocarcinoma of the cecum of the so-called carcinoid type.

On gross pathologic examination of the cecum, the tumor (fig. 1) was found to measure approximately 4 cm. in diameter; it presented a characteristic orange-colored appearance on cut section. The neoplasm was situated approximately a half inch (1.27 cm.) from the base of the appendix and this rudiment was not involved. On histopathologic examination (fig. 2) it was found to be an adenocarcinoma, grade 2, of the "carcinoid" type with involvement of the regional lymph nodes. The cells of this tumor were found to contain granules which reduced silver. Pathologic examination of the tissue removed from the rectum showed the tissue to be polypoid carcinoma, grade 1, without glandular involvement.

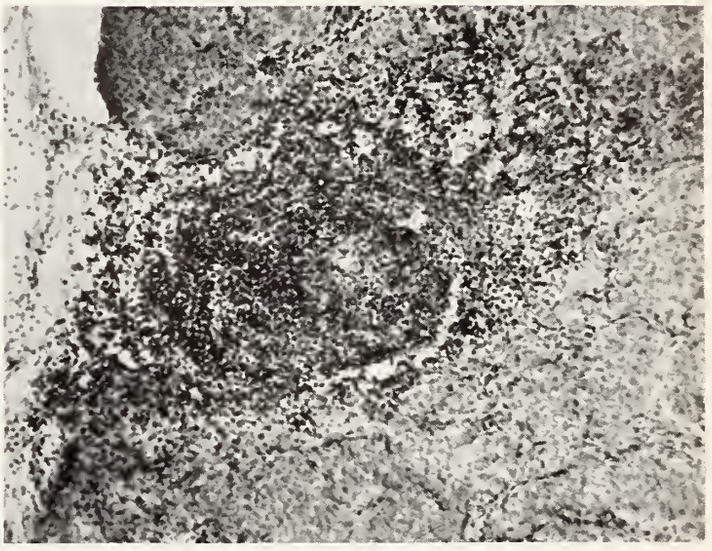

Fig. 2. Section of same tumor as that shown in Figure 1. The cells of this tumor contained granules which reduced silver (hematoxylin and eosin; x135).

Summary and Conclusions

It is generally conceded at present that the so-called carcinoid tumors arise from the Kultschitzky cells which are found in the base of the crypts of Lieberkühn. The ability of the cells of this tumor to reduce silver provides the surgeon with a postive means of diagnosis, although if ordinary hematoxylin and eosin preparations are used, the arrangements of the cells in groups will be characteristic enough. On gross examination the surgeon may gain an impression of the nature of the tumor by the yellow color which, in most instances, is present. Although there are those who still deny the malignancy of carcinoid tumors, it becomes more obvious as more cases are reported that actually they are true carcinomas.

Reference

1. Wyatt, T. E.: Argentaffine tumors of the gastro-intestinal tract: report of three cases; one with distant metastases. Ann. Surg., 107:260-269, (Feb.) 1938.

In a ten-year tuberculin-testing program in rural and town schools in four counties in Minnesota the percentage of reactors has fallen from 14.1 to 6.75 per cent. The decrease is attributed to a careful follow-up of all positive reactors, with an intensive search for the source of the infection. Contact with open cases of tuberculosis was broken by hospitalization of the case or placing the children in a home free from tuberculosis. All teachers and school personnel were included in the plan.

CASE REPORT

CONTACT DERMATITIS DUE TO NAIL POLISH

WILLIAM SAWYER EISENSTADT, M.D.
Minneapolis, Minnesota

NAIL polish was introduced some twenty years ago. However, not until 1937[1] was there any report in the literature of contact dermatitis due to nail polish. The absence of reports and its sudden appearance in the literature indicate that nail polish as a cause of dermatitis has been overlooked. The reason, however, is self-evident because of the peculiar distribution of the eruption. Even though the nail polish is applied on the fingernails, the eruption usually appears on the eyelids, face, neck or arms.

Case History

Miss H. O., aged thirty-two, was referred on January 8, 1941, because of an eruption of one year's duration. The dermatitis involved both alæ nasæ, both eyelids, and the right side of the face extending to the lobe of the right ear. The eruption was somewhat patchy in distribution, erythematous and scaly, with very mild evidence of vesiculation.

The patient stated that the eruption first appeared in December, 1939. At that time she complained of intense itching, puffiness of the eyelids, and a burning sensation on the right side of the face. Aside from an acute episode of hives, which she ascribed to the ingestion of tomatoes ten years previously, her familial and personal allergic histories were negative. The patient's occupation was that of a buyer in a department store where she handled fabrics, mostly rayon and printed cotton. The character and location of the eruption did not suggest an atopic etiology. A contact dermatitis was suspected, especially one due to cosmetics.

Patch tests of the following substances were applied: lipstick, face powder, perfume, cologne, mascara, rouge, rayon, soap, printed cotton, and nail polish. The patient was instructed to return in forty-eight hours, but was to remove any patch test that itched considerably. After thirty-six hours, the itching at the site of the nail polish patch test became so intense that she removed it. When the patient reappeared in the office that same afternoon, an elevated papulovesicular plaque was noted at the site of the nail polish patch test. All the other patch tests were negative. The patient was then instructed to remove her nail polish. Under mild local therapy, the dermatitis disappeared within three to four days. The patient was then tested with the clear lacquer base and a different shade of the same brand of polish. Both of these patch tests were markedly positive, indicating that it was the lacquer base and not the dye which was the cause of the dermatitis.

Discussion

The above case illustrates many points. First of all, any skin eruption, atypical in character, location, and distribution, should be suspected of being due to contact to an offending substance. Second, contact dermatitis can be exceedingly polymorphous[2] in character, varying from an erythematous to a vesicular or pustular eruption. Third, in all cases where cosmetics are suspected as a possible cause of a dermatitis, nail polish should be included in the testing.

TRANSMISSION OF BACTERIA IN VENTILATING SYSTEMS

In present-day air conditioning systems 90 per cent of the cooled air is often recirculated. The redistribution of air from an infected space to noninfected areas might conceivably become a factor in the spread of disease. In a recent study† of the rôle of ventilating systems in the transmission of microörganisms, bacteria (B. subtilis spores), which can be readily distinguished from other organisms usually found in air, were introduced in two different ventilating systems and the distribution of the spores was studied. The first ventilating system, which was provided with a paper-tissue filter, was located in a small auditorium. In one instance the spores were introduced beyond the filter and were thus not filtered, and in another experiment the spores were introduced in front of the filter and the air carrying them was filtered before being circulated. Fifteen minutes after the spores were introduced beyond the filter, analyses indicated the presence of 21.9 organisms to 10 cubic feet of the air in the auditorium. One hour after the spraying of the spores no organisms could be found in the air. Fifteen minutes after spraying spores in front of the filters only 3.7 organisms were present in 10 cubic feet of the air and after an hour these too had disappeared. In another series of experiments spores were introduced at different points in the ventilating system of a large building. Analyses of the air in two rooms of the building showed a maximum concentration of organisms during the spraying, which in these experiments lasted for a twenty-minute period or during a short period (one-half hour) thereafter. The number of organisms then decreased rapidly and within a relatively short time the count returned to a normal level. This rapid decrease is attributable to the dilution factor, and to the action of the filter, as well as to the loss occasioned by surfaces such as the walls and floor. These experiments were made under the most favorable conditions for the transmission of bacteria in ventilating systems, the number of spores being far in excess of that which might be possibly expected to occur normally and the spraying being done at advantageous points, and they demonstrate that bacteria may be spread in this way, although the menace seems slight. The problem merits further study from the point of view of public health.

HISTORY OF MEDICINE IN BROWN COUNTY

Compiled by George B. Weiser, M.D.

THE medical profession was well represented in the early settlement of Brown County, which was created by an act of the Legislative Assembly of the territory in February, 1855. According to well-established tradition, Brown County was named in honor of that picturesque frontier character, Joseph Renshaw Brown, early legislator, Indian agent, soldier, newspaper publisher, inventor, founder of cities and all round leader of men. Even for these days, with their broad stretches of unoccupied land, it was a county of tremendous proportions, covering approximately 42,000 square miles of territory and embracing all that part of what is now Southwestern Minnesota between the Iowa boundary on the south and the Minnesota River on the east and north, and in addition thereto all that part of what is now South Dakota lying east of the Missouri River and north of Sioux City.

In the time of its creation the only white settlers within its vast borders, excepting, of course, those attached to the government agencies and the Indian Missions on the new Sioux Reservation, were the thirty or more men, Germans, who had come out from Illinois the previous fall for the purpose of establishing a townsite for the Chicago Land Society. Partly because of the lateness of the season, they had located for the winter in a sequestered spot along the Minnesota River in what is now the township of Milford. These were the settlers who, with the arrival of some twenty additional members of the society about the middle of the following May, founded the town of New Ulm just a little more than three months after the county's creation.

In February of the following year the newly established village was officially designated as the county seat. Unlike the many other towns which had come into existence in the southern part of the territory immediately following the promulgation of the treaties of Travers des Sioux and Mendota, New Ulm can hardly be said to have been a hit-and-miss settlement, which just happened and then grew up. Instead, it was a carefully planned colonization effort in which two distinct organizations played an important part—one, the Chicago Land Society, organized in 1855; the other, the Turner Colonization Society, which came into being a year or two later.

Both of these organizations were made up almost entirely of Germans, many of them being emigrants who had been compelled to flee the old country as a result of the failure of the liberal revolution in Europe in 1848. They were all well schooled and among them was a very large percentage of highly trained artisans.

They came here at an inopportune time, during a period of great business depression. The urge which prompted the organization of their societies was practically the same in each instance—dissatisfaction with economic conditions, disgust with the welcome accorded them by the older settlers and an almost universal desire among them to found a community somewhere on a new

frontier where they could work out their social and economic problems in their own way, free from the bigotry and class hatred which characterized their first introduction to American equality and freedom. The Know-nothings, a secret political party in the United States in 1855, were opposed to foreign immigrants. Their principal tenets were opposition to the naturalization of foreigners and to their eligibility to hold office. They also advocated uncompromising antagonism to Roman Catholicism. Many of these early settlers were of that Christian faith. This society flourished in Chicago and in the East, and made it very unpleasant for foreigners.

The first step, as we have seen, was taken by the Chicago group in the founding of New Ulm in 1855. The next year representatives of the Cincinnati Society appeared on the scene and by reason of their stronger financial setup, were easily able to take over the original townsite by purchase and bring about a harmonious merger of the two organizations. Nothing like a deal of this kind, as far as we know, has ever occurred in Minnesota history. From this time on, for several years at least, the sun seemed to shine on the pioneer adventure. Kindred spirits in all parts of the old frontier were attracted by the courage and initiative of these resolute pioneers, and the growth of the new community was unusual.

In 1857, for example, when the town was only two years old, the special census shows a population of 478. In 1859 the first newspaper was started. There were fifty-four births in New Ulm that year. In 1860, when the regular census was taken the population was 635, the total population of Brown County being 2,300. During the Indian Massacre nearly 200 buildings were burned, either by the Indians, or by the defenders, to prevent them from falling into the hands of the attacking savages. All that remained standing were the twenty-five or thirty buildings within the barricades. Within these had to be crowded some 1,500 inhabitants, refugees and neighborhood defenders.

Outside physicians and surgeons who came to the aid of New Ulm during the second attack were Dr. Asa W. Daniels of Saint Peter, who had been one of the earliest surgeons at Fort Ridgley and later the government surgeon and physician for the Lower Reserve; Dr. Wm. R. McMahon of Mankato; Dr. Otis Ayer of Le Sueur, and Dr. W. W. Mayo of Le Sueur, father of the famous Mayo Brothers of Rochester.

In the early nineteen hundreds Dr. Valin, pathologist at St. Peter Hospital, started a class for practical instruction in bacteriology and urinalysis at New Ulm. This class consisted of Dr. O. C. Strickler, Dr. L. A. Fritsche and Dr. George B. Weiser. Dr. Valin came to New Ulm every week for a period of several months. He was an able instructor but somewhat irritable and eccentric at times.

During the early years the following practiced midwifery in New Ulm and the surrounding country: Frau Ottomeyer and Mrs. Schmidt in New Ulm; Mrs. Gluth in Milford township, and Mrs. Kloecke in Sigel township.

Hospitals of Brown County

It was largely as a result of the diphtheria epidemics in the eighties that interest was aroused among the residents of New Ulm in building the **Saint Alexander Hospital.** Rev. Alexander Berghold, who was instrumental in starting definite action, solicited the citizens for funds and met with generous response.

A house and lot were contributed by Mrs. Mary Schulz and the hospital was opened in 1883, with a capacity for twenty patients. Whatever the equip-

ment was, we know at least that it provided "Warmbäder, Kaltbäder, Turkishbäder" and that the "Preis von 25c für ein gewöhnliches Warmbad ist ein so niedriger dass sich auch der Aermster diese Wohlthat zu gniessen im Stand ist." The first house physician was Dr. O. C. Strickler. Other staff members were Drs. L. A. Fritsche, Jacob L. Schoch, C. B. Hirsch and George B. Weiser.

The Saint Alexander Mutual Aid Society was organized at about the same time the hospital was opened. The membership fee was 50 cents a month for men and 25 cents a month for women, in return for which the members received free hospital service in case of illness.

The Saint Alexander Hospital in 1884 was renamed the **Loretto Hospital.** It was conducted by the Poor Handmaids of Jesus Christ, and was started with a staff of six Sisters from the Provincial Mother House, Fort Wayne, Indiana. Venerable Mother Prudentia was the first Mother Superior.

The rapid growth of the hospital services necessitated a new addition in 1886, a third addition in 1900, and a fourth in 1911.

On November 27, 1912, the corner stone of the present Loretto Hospital was laid by Rev. Father Schlinkert, and on June 15, 1913, the building was dedicated by Archbishop John Ireland.

The present building is of modern, fireproof construction and is equipped with all modern appurtenances necessary for a standard hospital. It has a bed capacity for forty-five patients, with eight bassinets. A home for the aged with a bed capacity of fifty-six is maintained in a separate building. All practicing physicians in New Ulm are members of the hospital staff.

Union Hospital, opened to the public in 1914, was established through the agency of the Protestant people in the community and was organized as a stock company with directors and officers.

The hospital is housed in a three-story, fireproof building and has a capacity of sixty-two beds and nine bassinets. All physicians practicing in New Ulm are members of the staff. Union Hospital is thoroughly equipped and standardized to conform with the regulations of the National Hospital Association.

Saint John's Hospital at Springfield, Brown County, was founded in 1901 through funds obtained by subscription. It has a capacity of nineteen beds and five bassinets.

Sickness and Epidemics in Brown County—1860-1900

The *Saint Peter Tribune* of February 22, 1865, stated that there were fifteen cases of smallpox in and around New Ulm. In 1867 smallpox broke out in New Ulm in a violent form. In 1869 the *New Ulm Post* reported more illness among the children than at any time since 1862. There were seven or eight deaths resulting from summer complaint.

A newspaper reference in 1876 notes a fatal malady among the children which had caused a number of deaths. Dr. Berry believed it to be an aggravated form of sore throat caused by damp weather and impure effluvia from the gutters and cesspools. The following year there were several newspaper references to the fact that Dr. Berry was well supplied with fresh vaccine virus and would gratuitously vaccinate all those who applied. This may or may not have been an indication of smallpox in the vicinity. At any rate it shows a greater consciousness of preventive measures.

In 1879 there was an outbreak of diphtheria in Iberia, Stark and Cottonwood townships. Early in 1880 the *New Ulm Post* stated that three of the most afflicted families in Sleepy Eye had lost a total of fourteen children within four-

teen days. In Mulligan township nineteen children had died within three weeks. The following June several physicians from Brown County and Blue Earth County met to discuss the situation. Occasional deaths still occurred throughout Brown County during the fall and by January of the following year another epidemic was well started. This continued through the year 1882 and in the winter of 1883 cases occurred in all sections of the county. New Ulm seems to have had few cases in proportion to its population. This may have been due to the fact that the rural communities did not have the benefit of local Boards of Health and that quarantine was less strict.

In 1885, 1886 and 1887 there were scattered cases. Diphtheria seemed to be the disease which affected the county to any extent and it was largely due to concern over the fatalities resulting from this disease that the first hospital was established in New Ulm.

Scarlet fever and diphtheria prevailed during the nineties and throughout the next few years various counties were affected. In the winter of 1893 there were a number of cases in Stark and Sigel townships. In Sleepy Eye alone twenty-three cases of diphtheria were reported. Dr. Fritsche, health officer of New Ulm, reported that scarlet fever had been prevalent to a small extent for many years in New Ulm but did not become epidemic until September 18, 1892. Unfortunately the first cases were not reported to the authorities because of fear of quarantine. On December 2 sixty-two families in the city had been affected and the City Council enforced a rigid quarantine regulation. This regulation met with opposition from the Lutherans of the city since it interfered with regular gatherings of the congregation. Before the regulation went into effect twenty-one families had been attacked. Three weeks after enforcement of the regulation there were only three cases. By April 2 there had been 210 cases and twenty-six deaths. The majority of cases were among children under ten years of age.

Activities of the health officer also included the examining and killing of glandular horses in Sleepy Eye. The health officer in Sleepy Eye at that time was Dr. J. W. B. Wellcome. Those who served New Ulm from time to time were Drs. Weschcke, Fritsche and Strickler.

Brown County Medical Society

The Brown County Medical Society was organized October 8, 1895. All the physicians of the county were present at the organization of the Society except Doctors Rothenburg and Adams.

The following were the first officers:

President—Dr. J. W. B. Wellcome, Sr.
Vice President—Dr. C. B. Hirsch.
Secretary—Dr. O. C. Strickler.
Treasurer—Dr. T. Sullivan.
Executive Committee—Dr. L. A. Fritsche, Dr. J. W. B. Welcome, Jr., and Dr. T. Sullivan.

In January, 1896, there was another meeting at which Dr. Pucklitsch read a paper on the cause and treatment of pneumonia. The newspaper account said that the Society would hold its regular monthly meeting, so we may conclude that the organization was pretty well established. This meeting was attended by physicians from Redwood County and other surrounding localities. Dr. George B. Weiser read a paper on "Infectious Diseases."

At a later meeting of the Society Dr. Todd of Minneapolis and Dr. McDavitt of Saint Paul read papers. Dr. Weiser read a paper on "Administration of Anesthetics."

Redwood-Brown County Medical Society

During the World War the charter of the Brown County Medical Society was revoked by the arbitrary ruling of the State Medical Association. Charges of disloyalty were preferred, but there was never an investigation made to sustain the charges, nor could disloyalty have been substantiated among the members. After the war the State Association, without apology for the actions taken in revoking the Society's charter, requested the former members of the Brown County Medical Society to re-organize under the name of the Redwood-Brown County Medical Society.

On December 23, 1919, at the office of Dr. J. C. Rothenburg at Springfield, the members of the former society met to organize the new society. Dr. Rothenburg acted as temporary chairman and it was moved and carried that the temporary organization be made permanent. The following officers were then elected:

President—Dr. C. C. Walker, Lamberton.
Vice President—Dr. E. Jamieson, Walnut Grove.
Secretary-Treasurer—Dr. W. A. Meierding, Springfield.
Board of Censors—Dr. J. Adams (3 yrs.), Dr. M. Sundt (2 yrs.), Dr. Mary Strickler (1 yr.).

The Society at the present time (1940) is in a flourishing condition, having thirty-one members. Quarterly meetings are held with papers and discussions by outside physicians from the University of Minnesota, and the Mayo Clinic as well as by local physicians. Attendance of the full membership is usual.

Physicians and Surgeons Located at New Ulm

Dr. C. H. Blecker advertised in the New Ulm *Pioneer* as Deutscher Arzt from June 1, 1858, to February 24, 1859. The *Pioneer* also contained the cards of Jacob Fleck and wife in 1858. Dr. Fleck was a barber who did bloodletting, extracted teeth, et cetera.

Dr. J. B. Calkins came in 1852 and remained about two years. He held a claim of land at Leavenworth.

Dr. John Kaula, a Hungarian, a graduate of the University of Budapest (about 1840), came to the United States as a political exile. He was a follower of Louis Kossuth, the Republican leader of the Revolution in Hungary in 1848. Dr. Kaula came to the United States in 1849 and practiced in Chicago until the founding of the New Ulm settlement. He was a good botanist and prepared roots and herbs whenever needed in the form of concoctions. He used quinine, mercury and salts liberally. He underwent all the exposures incident to pioneer life. It is said that he walked five miles in the snow to attend a case in confinement. He retired in his later years but remained in New Ulm until his death which occurred in his eighty-fifth year in 1892.

Dr. Carl Weschcke advertised as Praktiker Arzt and Wund Arzt as early as June, 1860. He was born in Saxony in 1831. He was educated in that country, passed through the Military Surgery Department of the University of Berlin, then through the University of Griefswald, graduating in 1856. He then attended Halle University where he served in the army one year, according to law.

He came to New Ulm in the year 1860 and he and Dr. Kaula were the only resident physicians during the Indian Massacre in 1862. Dr. Weschcke was employed as Military Surgeon for soldiers. In 1868 he went to California,

where he remained several months. He became sick, however, and returned to New Ulm. Dr. Weschcke was the first pharmacist in Brown County and in 1866 established the first drug store in New Ulm, known as the Pioneer Drug Store, now the Epple Drug Store. Dr. Weschcke was civic minded. In 1870 he was elected to the New Ulm City Council and subsequently was appointed to the office of mayor in 1877. He served in that capacity for fifteen years. He died at New Ulm in the year 1906.

Dr. Winkelmann advertised as Arzt, Wund Arzt, and Geburtshilfer Zahn Arzt, from March, 1858, to April 14, 1859.

Dr. Truman R. Humphrey was a native of Vermont. He received his medical education in Boston and was one of the early white settlers in western Brown County. His first practice was in Stoughton, Massachusetts. Thereafter he practiced in Thornton, New Hampshire, until 1859 when he moved to Hokah, Minnesota, where he took a homestead. In 1864 he took a claim three miles southeast of Sleepy Eye in Albin township, and remained on the farm for forty years. He practiced medicine in that community over a period of twenty-five years. He was coroner for Brown County from 1887 to 1892. After retiring from the farm he moved to Sleepy Eye, where he died in 1911.

For many years Dr. Humphrey was one of the most influential residents of western Brown County. He and his wife took an active part in the development of the social and economic conditions in that part of the county.

Dr. August Westphal advertised as Zahn and Augen Arzt from February, 1860, to March, 1861. He opened the first school on December 17, 1857, and was its teacher. After the Indian War in 1862 Dr. Weschcke and Dr. Kaula had the field to themselves until about the year 1867.

Dr. Alfred Mueller was born in Berne, Switzerland, in 1835. There he obtained his literary and medical education, graduating in medicine in 1852. In December of that year he came to the United States, locating in New York City for a brief period. In 1856 he came to Minnesota, locating at Stillwater until 1861 when he was appointed Surgeon-in-Charge of Fort Ridgely where he remained until 1867. He was the only surgeon in charge during the battle with the Sioux.

After the military post was abandoned he moved to New Ulm where he followed the practice of his profession until 1889, retiring to his native Switzerland to pass his declining years. He died in 1899.

Dr. Mueller married Eliza Eichelberger who died in 1876. At the trying hours during the Indian outbreak at the fort she did not spare herself in nursing the sick and wounded men. Due to exposure and laborious efforts in ameliorating the sufferings of the sick, her health became undermined and this, it was believed, hastened her death. She was the Florence Nightingale of Fort Ridgely.

A monument has been erected by the state at Old Fort Ridgely to commemorate her labors in behalf of the afflicted during the siege of the Fort The monument has the following inscription:

> "Mrs. Eliza Mueller, wife of Dr. Alfred Mueller, born in Berne, Switzerland, April 21, 1831; died September 26, 1876. Thy Mission on Earth was unbounded Charity; Thy Reward is Eternal Peace."
>
> "Her valor and devotion to the care of the sick and wounded soldiers and refugees during and after the Sioux Indian Outbreak of 1862 will forever be cherished in the hearts of a grateful people."

Dr. Mueller was one of the outstanding physicians of this part of the country. While a student in Berne, Switzerland, he was an instructor in anatomy. When Dr. Fritsche visited him in Berne in 1889 Dr. Mueller took him to the Medical Museum to show him an anatomic specimen which he had prepared thirty-seven years before; it was still in good condition. Dr. Mueller was considered one of the best surgeons in this region. He served as chairman of the town board of New Ulm in the early days and was a member of the pension board. He was a member of the Blue Earth County and Minnesota Valley Medical Societies as well as the Minnesota State Medical Association.

F. Zur Netten, a German physician, practiced in New Ulm in the late fall of 1883.

Dr. G. A. Sellmer located in Lake Hanska and Linden township in 1873. He practiced there until 1890 when he decided to go back to Norway.

Dr. J. L. Wellner practiced in Brown County in the early eighties. He served as county physician for a time.

Dr. Marcel Zenopalsky advertised as Amerikaner-Deutscher Arzt and Wund Arzt from June 2, 1860, to June, 1861. His advertisement in a New Ulm paper stated he could prevent and cure scarlet fever for 25 cents. He later moved to Blue Earth County.

A **Dr. Wilson** located at New Ulm in 1870, remaining until November 3 of the following year. He died in 1872 and is buried in the town of Leavenworth, Brown County. He was addicted to drink and when imbibing entertained his company by singing such songs as "Coming Thru the Rye."

A **Dr. M. W. Scott** came from Morristown, Minnesota, in 1870, or thereabouts, and located in New Ulm. After a year he moved to the Dakotas. His fees were 25 cents in town; 50 cents in the country.

Dr. A. F. George, evidently a college graduate, started practicing in New Ulm in July, 1870, and remained for a brief period.

Drs. Weems and Menning opened offices in New Ulm in May, 1872. The partnership was dissolved the following September and Dr. Louis Menning continued the practice until March, 1873. He later located in Ohio.

Dr. J. W. B. Wellcome located in New Ulm in 1871 and remained until 1874; he returned for a few months in 1879. Dr. Wellcome was born in New Portland, Maine, in 1828. At the age of sixteen he entered Burnhame High School where he remained three years. He then studied medicine, received his diploma and, in 1856, went to Wisconsin where he practiced until 1858. The following year he located at Garden City, Minnesota. In 1883 he received a diploma from St. Louis College of Physicians and Surgeons. In 1862 he was appointed examining surgeon for the drafted men in the Civil War, with offices at Mankato. In 1863 he was first surgeon, substituting for Dr. W. W. Clark, who was ill. In 1872 he was appointed surgeon for pensions, holding the position for four years.

Dr. Wellcome assisted in forming the first medical society in the Minnesota Valley. He was at Garden City during the Sioux uprising in 1862. From Garden City he moved to New Ulm in 1871 and in 1874 located at Sleepy Eye where he continued the practice of medicine until the time of his death in 1906. He was an Active Free Mason, was civic minded and took an active interest in advancing the civic affairs of Sleepy Eye and adjacent community.

Dr. Wellcome, as was customary in those early days, acted as preceptor for several young men, namely—Dr. J. W. Andrews of Mankato, Dr. J. T. Burnside of Duluth, and his son, Jacob Burnside, Jr. Dr. Wellcome died of carcinoma of the neck.

Dr. B. Hofstetter located in New Ulm from October 20, 1871, until May, 1873.

Dr. Charles Berry, one of the leading practitioners of this community, arrived in New Ulm in March, 1873. Dr. Berry was born in Coleville, New York, in 1837. He studied medicine in Concord, New Hampshire, and in 1859 graduated at the University of Michigan; he also graduated from the University of Buffalo, New York, in 1870. Dr. Berry enlisted as an assistant surgeon in the 106th New York regiment and served until the Civil War closed. On account of impaired health he came to Minnesota in 1866, locating at Belle Plaine. In 1872 he commenced the practice of medicine at New Ulm, continuing until the time of his death, July 18, 1890.

Dr. William Wakefield, graduate of University of Michigan Medical College in 1882, located at New Ulm for several years, then moved to Lake Benton, Minnesota, where he continued practicing medicine for many years until his death.

Dr. Eli Kuhlmann located at New Ulm in the latter part of 1879 and remained there until October, 1881. He was a physician and chemist and ran a drug store. He gave special attention to chronic diseases. A year later he moved to Indiana, where he died.

Another physician who came to New Ulm in 1879 was **Dr. B. Carl,** whose real name apparently was **Carl von Neufert.** Dr. von Neufert was born in Bavaria in 1839. He attended the University of Wurzburg in 1865 and served as surgeon in the army in his native country. He practiced in Bavaria for ten years before coming to the United States. He practiced at New Ulm until November, 1884, when he moved to Colby, Wisconsin; later to Stevens Point, Wisconsin. His son, Carl von Neufert, F. A. C. S., became an eminent surgeon at Stevens Point, Wisconsin, where he began practicing in 1892. He has been made an honorary member of the State Medical Society of Wisconsin.

Dr. B. M. Randall, son of the well-known Fort Ridgely settler, Major B. H. Randall, located at New Ulm in December, 1884. He remained there until January, 1887, when he removed to Graceville, Minnesota, where he practiced many years. He was a graduate of Rush Medical College, Chicago, in 1883.

(To be continued in April issue.)

President's Letter

THE PATIENT-PHYSICIAN RELATIONSHIP

HISTORIANS tell us that history repeats itself, that discoveries of archeologists show as fine and as high a type of civilization in the dim past as we have now. Economists speak of the worries and the concerns of past ages, the modes of living under the then existing economic conditions, of dollar values, of periods of depression and times of plenty with waves of prosperity.

Today we find that the nature of people has not changed to any great extent; that the psychology of life has remained about the same; that thoughts which we might attribute to one century and people carry over into the next century; that the brotherhood of man in this so-called changing world still hinges around the Golden Rule.

The physician, since the time of Hippocrates, has believed in free enterprise in the practice of medicine. The physician-patient relationship is founded on faith and honesty, a sacred trust which has survived the vicissitudes of time. The men of our Association, more and more, are coming to believe in this relationship.

If we are to live in a democracy, true democratic principles in word and deed must prevail. There can be no half-way between state medicine and our present type of practice. The public has been and will be better served under our present method. We are banded together in a mutual help organization, not a trust or corporation for profit, with a firm and steadfast purpose of increasing the joy of living by aiding the people of our nation to better health.

We are coöperating with the government in national defense, giving of our time and knowledge without even ordinary compensation for our time. Many of our members are leaving their homes and practices at great sacrifice to enter military service. Can we be called selfish in our desire to protect a principle most dear to us?

We know that in private practice, faith plays a great part in cure when it overcomes fear. This faith causes the patient to follow his physician's bidding, and can only be found where the present type of practice prevails.

Civil governments and industrial compensation boards recognize this when they grant to an employe the right to choose his own physician and surgeon. When dictators and dictatorial powers prevail in our state and nation, democracy will fall and our people will become serfs and slaves to their will; then professional men will become puppets to their wishes.

We say it cannot happen here. Why do we believe this? Are we so sure of our strength? Unless we assert ourselves by giving to our clientele the best of medical accomplishment, both preventive and curative, and hold firmly to a feeling of friendship, collaboration and fair dealing with each other, we may find ourselves beset by the danger of having our liberties taken away from us and our opportunities dissipated by circumstances without our control.

It is well that we hold fast to that which has been tried and not found wanting, both in government and medicine.

TRENDS OF DISEASE

MUCH of the present-day news is so depressing that we are inclined to grasp at reports that show favorable trends. And although statistics must be taken with caution, when properly compiled and interpreted they do indicate trends. The statistics put out by the Metropolitan Life Insurance Company meet these requirements and each year the mortality rates of this company duplicate those of the country at large.

During the past thirty years the mortality rate has fallen 40 per cent. This progress is accounted for largely by the cutting down of deaths in infancy, childhood and young adulthood. The decline in mortality rate, however, has been present in all age groups.

The average length of life of all policy holders in this insurance company is sixty-three years, which constitutes a gain of sixteen years in the past thirty years.

One of the most outstanding reductions in death rates has been that in pneumonia. In 1940, this rate was 35.5 per 100,000; in 1939, 42.8; in 1938, 50.6; and in 1937, 66.9. In the past four years the mortality has been cut in half. Serums and drugs are entitled to the credit for this progress.

In the case of tuberculosis the mortality last year was 44.3 per 100,000 compared with 80.9 ten years ago, and 224.6 thirty years ago.

The childhood diseases continued in 1940 to be less of a menace than the year before. The mortality of scarlet fever, measles, diphtheria and whooping cough combined was 2.9 for 100,000, less than that for measles alone ten years ago.

It is pleasing to note, too, that last year there was a decline in the mortality due to appendicitis and puerperal fever.

On the other side of the picture the mortality due to chronic diseases characteristic of middle and later life, namely diabetes, cancer and vascular diseases, has increased. This is to be expected as the proportion of the population in the older decades is increasing.

Doubtless numerous factors account for the improvement in the health of our citizens. Publicity campaigns which call the attention of public and profession alike to the need for taking remedial action play their part. The remedial steps taken in response to publicity campaigns are fully as important. Improvement in public sanitation and control of contagion is without doubt more important in the betterment of public health than all other factors combined.

DR. IKEDA VINDICATED

IN OUR ISSUE for October, 1940, appeared an editorial on the subject of "State Licensure of Laboratory Technicians" by Dr. Kano Ikeda, pa-

thologist at the Miller Hospital in Saint Paul. The editorial, in brief, advocated the continuance of the Registry of Medical Technologists of the American Society of Clinical Pathologists, which has been in operation since 1928 and in which some 6,000 medical technicians have voluntarily met the requirements and registered. He could see no reason for changing to state licensing with forty-eight different standards subject to political influence and control. Reference was also made to the organization known as the American Medical Technologists, composed of technicians not registered with the Society of Clinical Pathologists, which for a fee of five dollars issues a certificate M. T. so like the one issued by the Registry as to be confusing to the uninitiated.

The editorial aroused a spirited response from Dr. R. B. H. Gradwohl of the Gradwohl Laboratories, Saint Louis, in the form of a communication submitted for publication in the journal. Not wishing to present a battlefield for a controversy over the question whether medical technicians and the public weal would be better served by registration in individual states than by continuing the present national Registry of the Society of Clinical Pathologists, we declined space to Dr. Gradwohl's communication. The communication, we are informed, appeared in *The Gradwohl Laboratory Digest* with additional material consisting of a letter to Dr. A. D. Cutter, Secretary to the Council in Medical Education and Hospitals of the A.M.A., making inquiry regarding the authorship of a statement attributed by Dr. Ikeda to Dr. Cutter, and also Dr. Cutter's reply denying his having made such a statement. Copies of this *Laboratory Digest,* according to report, have been widely circulated in Minnesota and perhaps elsewhere in an obvious attempt to discredit Dr. Ikeda and, therefore, his point of view in the eyes of the profession.

When Dr. Ikeda called Dr. Cutter's attention to the latter's statement which appeared in one of his letters to the effect that "the Council was in no position to feel that a state board of examiners in medical technology would represent any advance over present methods of control in this field," Dr. Cutter corrected himself both to Dr. Ikeda and Dr. Gradwohl.

Dr. Ikeda is well known in the Twin Cities where he has acted as pathologist at the Minneapolis General, Saint Luke's and the Miller Hospitals. His activities in trying to raise the standard of training for medical technicians and in combating dishonest advertising on the part of low-grade commercial schools for technicians are nationally known. Any aspersions, therefore, on Dr. Ikeda's honesty and truthfulness are resented and we are glad to give space to explain the facts which led to Dr. Gradwohl's accusations. An admission by Dr. Gradwohl in his *Laboratory Digest* of the error in his judgment of Dr. Ikeda, which opinion has been broadcast in this same *Laboratory Digest,* would serve to undo, in part, the injustice he has done to Dr. Ikeda, and would close this chapter of a controversy which doubtless has two sides and upon which other chapters will doubtless be written in the future.

PREMARITAL EXAMINATIONS

SOUTH DAKOTA, Illinois and Wisconsin now have laws on their statute books which require that those who contemplate matrimony exhibit to the County Clerk of Courts certificates showing that they have recently submitted to tests for syphilis and that the reports show negative reactions. Until this is done, no marriage license can be issued.

As long as States adjacent to those mentioned above have no legislation covering these matters it is easy for those so desiring to evade the provisions of these laws. People living in Sioux Falls, South Dakota, for example, can, and frequently do, go to Luverne, Minnesota, or Rock Rapids, Iowa, a distance of thirty-five miles in either instance and get married without having to pay any attention to the South Dakota law. A recent Associated Press dispatch carrying the date line of Des Moines, January 11, stated that at least 22,000 surplus couples exchanged vows in 1940 in Iowa. A bill to remedy this situation is being introduced in the present Iowa legislature. Such a measure passed the house last session but died in a senate committee.

"This increased marriage business is not very healthful," Dr. Walter L. Bierring, Iowa Health Commissioner and former President of the American Medical Association is quoted in the same despatch as saying. "It dramatizes the need for such legislation in this state."

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

PREPAYMENT PLANS FOR MEDICAL SERVICE

Voluntary group medical care is probably the most generally discussed of all civilian projects before the medical profession today.

Many voluntary plans have been started in many parts of the United States, some under private sponsorship and some under the ægis of state and county medical societies. So far none of those which are under medical society management have been in existence long enough to provide much material for judgment as to their worth.

Enabling acts have been obtained in most cases but the acts are so drawn that groups of persons outside of organized medicine may, in nearly all cases, take advantage of them and set up competing group medical plans. Also separate units of medical association members may operate independently under the act. Such, at least, has been the experience to date.

A number of prepayment plans of the contract type have been in existence in various parts of the country for a considerable length of time. Increasingly corporations have been employing part or full-time medical men in behalf of their employes and insurance companies are developing plans for hospital, surgical and medical benefits. More and more attention is being given by state medical associations and their component units to the whole question of prepayment plans for medical service.

For Government Support

Also there is still pressure for government supported compulsory sickness insurance and quite recently even Thomas E. Dewey of New York, defeated candidate for the Republican nomination, with an eye, no doubt, to 1944, quite definitely ranged himself in favor of new plans for medical care for the American people. Whether the arrangement should be compulsory and tax supported he did not say, though he took care to stipulate that medical men should be in control of the service and the patient should have his choice of physician.

Thus top flight politicians are seeing the value of medical care as campaign material and the subject is obviously a live one within and without the ranks of medicine today.

Conference Reports

There is clearly a great need to accumulate and report upon experiences, to date, of all who are now experimenting in prepayment plans for medical service.

This need was recognized at the Chicago National Conference on Medical Services (successor to the Northwest Regional Conference which formerly held its sessions in Saint Paul) with a group of reports under the following titles and speakers—"The Second Year," by Mr. J. D. Laux, executive director of Michigan Medical Service; "Why Are We Waiting," by W. D. Hartman, Macomb, Ill., and "What We Learned From Wisconsin Experiments," by Mr. J. G. Crownhart of Madison, secretary of the Wisconsin State Medical Society.

The second year of the Michigan experiment still finds the project "in the red," according to Mr. Laux. The plan is not yet reaching low income groups and probably will not unless they can be solicited through the large industries. The fact that the Ford Company will remove its entire group from Michigan Medical Service to an insurance company plan, March 1, may mean a setback.

As noted in the February issue, the Wisconsin experiments have been abandoned, and, though figures and facts were not conclusive, it was quite obvious that no ready made public demand existed for such prepayment services.

Trouble in New York

Medical Expense Insurance has been considered carefully in New York and a plan has been worked out under the name of "Medical Expense Fund of New York," which is now in the process of organization under sponsorship of the state and county medical societies concerned. To facilitate the project, enabling legislation was sought and obtained from the state legislature; but, as noted above, the legislation was not limited to projects organized and sponsored by organized medical groups. The result has been, according to the *Westchester Medical Bulletin,* that no less than six prepayment plans are now operating or are in process of organization under the Act. Among them are the Group Health Coöperative, Inc., the American Plan for Medical and Surgical Care, Inc., the Medical Guild Foundation, Inc., the Association for Prepaid Medical Care, Inc., and Associated Health Foundation, Inc., besides the Medical Expense Fund. As a result, it is not unlikely that the whole program will be weakened and discredited before the public. The law, in this case, does not limit or specify the number or kinds of corporations which may attempt to qualify under it except that such a corporation must operate on a nonprofit basis. To date, protests to the State Department of Insurance have been unavailing.

New Jersey's Act

In New Jersey, on the other hand, medical society sponsored insurance is only just being organized; but an enabling act which permits only the state medical association to conduct such insurance has been obtained. The Ohio State Medical Association is hoping to get a similar bill through the Ohio legislature this year. The California State Medical Association is embarked on a big scale plan for voluntary health insurance at low premium; but the efforts of the state medical association to meet the demand by this means may be thwarted before it has had a chance to prove itself by the public demand for compulsory state supported sickness insurance made recently by the governor.

In Illinois

Dr. Hardin of Illinois told the Chicago meeting that in view of these and many other experiences, Illinois would wait for better figures and more complete results. In Illinois there appears to be no great public demand for prepayment plans, and the difficulties of selling such insurance to the people who need it most are clearly enormous.

At the Forefront

It was gratifying to Minnesota delegates to the Conference to find that in two exceedingly important departments, Minnesota seems to be at the forefront among the states.

The Minnesota plan for medical care of all social security and welfare clients was much further developed than in the other states represented, though extension of the plan to the big cities still lags. Mr. Walter Finke, director of the Division of Social Welfare, Dr. H. E. Hilleboe, Chief of Medical Services, and Dr. A. W. Adson, Chairman of the State Medical Advisory Committee, outlined the county function of county medical advisory committees here, and of the state advisory committee which operates as part of the division. Rural services in other states appear to be chaotic by comparison; but in some of the cities, notably Chicago, relief patients are permitted to choose their own physicians, just as they are in rural districts here, and the city welfare board pays the fee.

Center Courses Outlined

With the extraordinary development of medical programs at the University Center for Continuation Study, sponsored and assisted by the Minnesota State Medical Association, as outlined at the Conference by Director W. A. O'Brien, postgraduate medical education in the state has moved far ahead. Center courses afford intensive training for practicing physicians under ideal conditions and they are supplemented to a growing extent by the continuous service provided in the "subject-of-the-month" packets, sent free upon request to any member from association headquarters.

MINNESOTA LEGISLATURE IN SESSION

The 1941 session of the Minnesota Legislature convened on January 7, and is now in full swing. Approximately 1,200 bills have been introduced so far in the Senate and House. The Committee on Public Policy of the Minnesota State Medical Association has reviewed a large number of these bills, some of which directly concern the practice of medicine.

A bill regulating non-profit hospital service plan corporations passed the House of Representatives by a vote of 103 to 6. It has been unanimously recommended for passage by the Senate Public Health Committee, and will soon be up for a final vote on the floor of the Senate. This bill was very carefully considered by the Council of the Minnesota State Medical Association, and should prove very acceptable to the medical profession. Prepaid hospitalization as developed by the Minnesota Hospital Service Association, was started in Saint Paul in 1933, and has grown until today 380,000 persons throughout Minnesota are covered by group hospitalization in this plan.

A bill has been introduced in both the Senate and House to restrict the sale of paregoric to sales made upon the prescription of physician and surgeon. Under existing law, a druggist may sell 2 ounces of paregoric in forty-eight hours to a person without a medical prescription. This loop-hole has made it possible for addicts to go from one drug store to another and purchase unlimited amounts of the drug. This legislation was requested by the Federal Bureau of Narcotics because of the large increase in the sale of paregoric to drug addicts who find it increasingly difficult to obtain morphine and other derivatives of opium.

A bill has been introduced in the House to permit fraternal organizations to furnish medical services to their members and to permit such organizations to enter into contracts with physicians to furnish such medical care. According to legal advice, fraternal organizations cannot, under present laws, designate a physician to furnish medical care to their members. The proposed bill would undoubtedly tend to destroy free choice of physician.

A bill has also been introduced in the Senate and House requiring every motor vehicle using the public highways to be covered by liability insurance in a minimum amount of $1,000 for one injured person, or $2,000 for each accident. Such a law would greatly facilitate the payment of many hospital and medical bills that now go unpaid following accidents. The information available indicates that approximately four out of five motor vehicles do not carry liability insurance.

A bill has been introduced to appropriate money to assist counties employing a public health nurse. A bill has also been introduced to appropriate money for so-called after-care for persons afflicted with Tuberculosis. Both of these bills must first be approved by the Senate Finance Committee and the House Appropriations Committee.

There will undoubtedly be other bills introduced which concern the practice of medicine and they will be carefully scrutinized by your Committee on Public Policy.

Committee on Public Policy,
By: L. L. Sogge, M.D., *Chairman.*

IN THE WASHINGTON HOPPER

To any one, who innocently fancied that military preparedness would occupy the 77th Congress to the exclusion of any but the most pressing civil and domestic measures, the list of new bills looking to the improvement of the national health already introduced will be illuminating.

There are, for instance, three bills introduced by Senator Murray of Montana; the first, to provide federal appropriations for compensation for disability or death of workers from silicosis or other dust diseases; the second, to provide sums as high as $37,000,000 in 1946 and not to exceed $17,500,000 in subsequent years for prevention, treatment and control of tuberculosis to be administered and state plans to be approved by the United States Public Health Service; third, to appropriate up to $3,000,000 in 1943, to be given to the Secretary of Labor to provide more adequate protection to workers and their families from losses caused by disability or death from occupational diseases and to promote prevention and control of industrial conditions hazardous to health. State Plans to obtain aid under this appropriation would have to provide for administration by state labor departments or other agencies charged with administration of labor laws, not by state departments of health.

Tuberculosis, Cancer, Hospitals

Representative Elliott of California has introduced a bill for prevention and control of tuberculosis among migrant workers with an appropriation of $1,000,000 the first year, to be administered by the United States Public Health Service; and Representative Rogers of Massa-

chusetts has introduced a bill to provide $2,300,000 the first year for fostering research relating to cancer and for aid to establish a National Cancer Institute, all under direction of the United States Public Health Service. Besides aid to research projects this bill provides for aid to states, counties, cities or other political subdivisions for improvement and extension of facilities for diagnosis and treatment of persons suffering from cancer or suspected of having cancer, provided that "appropriate professional groups" coöperate with the plans and that preference, so far as treatment is concerned, is given to needy persons.

Representative Fulmer of South Carolina has introduced a bill for construction of hospitals which is identical with the Wagner-George bill for hospital construction introduced in the 76th Congress and passed by the Senate at that session. It was referred to the House Committee on Interstate and Foreign Commerce and died there when the Congress expired.

For Chiropractors

A new attempt to give chiropractors the right to treat injured federal employes entitled to benefits under the United State Employes Compensation Act, has been made in a bill introduced by Representative Toal of California; and Senator Capper of Kansas has once more introduced his bill for establishment and administration of state health insurance plans. This is the perennial sickness insurance bill sponsored by the American Association for Social Security which proposes an appropriation of no less than $50,000,000 for the year 1941 and, thereafter, whatever annual amount may be necessary for its ambitious program. Incidentally, the bill stipulates that *ALL* schools of practice duly licensed within the state shall have the right to furnish the medical benefits under the act.

For Needy, Blind, Cripples, Veterans

Two bills to provide medical and surgical aid to needy blind and to provide for education of all types of physically handicapped children were introduced, respectively, by Representative Patrick of Alabama and Representative Angell of Oregon, the one to be administered by the Social Security Board, the other by the United States Commissioner of Education and state departments of education. Appropriations for care for the blind would be $1,000,000 for the first year; for the handicapped they would be up to $11,580,000.

Representatives from five states have introduced bills for construction of new veterans' hospitals and for enlargement of existing facilities to the tune of 3,350 new beds at a cost of more than $9,000,000.

Reintroduced

H. R. 10,606, the bill to promote national preparedness through physical education, including athletics instruction and guidance in healthful living, died with the 76th Congress but has been reintroduced as H. R. 1074 by Representative Schwert of New York with specific reference to health education eliminated. This bill is sponsored by the American Association for Health, Physical Education and Recreation and proposes a federal appropriation totalling eventually no less that $200,000,000 a year! It carries a most unusual provision to the effect that the scope of activities to be carried on under it may be extended in any state apparently without any limit whatever if the legislature of that state decrees. The administration would apparently remain in the hands of the Department of Education.

To Exempt Students—Purify Streams

A bill to create a division of water pollution control in the United States Public Health Service has been introduced by Representative Spence of Kentucky. Annual appropriations not to exceed $50,000,000 will be made available, if the bill is passed, to prepare comprehensive plans for reducing pollution and improving sanitary conditions of all the navigable waters and streams tributary thereto of the United States; also for grants-in-aid to state or municipalities for construction of necessary treatment works.

Senator Murray also introduced a bill to commission any qualified physician or dentist selected for training under the Selective Service Act in the Medical Reserve Corps and then call him to active service according to the law; also to exempt all medical and dental students from training and service and to exempt such students who are members of reserve components of the land or naval forces, from active service without their consent except in time of war. This bill is identical with one introduced by Senator Murray in the last Congress.

For a Secretary of Health

A bill to establish a Department of Health at the head of which is to be a Secretary of Health, long advocated by the American Medical Association, has been introduced by Representative Pfeifer of New York. The secretary, according to this bill, must be a "member of the medical profession." If the bill is enacted, the Food and Drug Administration, the Bureau of Census, the Division of Vital Statistics, the Freedmen's Hospital and St. Elizabeth's Hospital, the Children's Bureau, all functions of the United States Public Health Service, the Bureau of Narcotics and the Health Department of the District of Columbia would be transferred to this department; also the whole or any part of any bureau, service or other agency of government primarily engaged in fostering or promoting health and sanitation.

In the Offing

That the ensuing weeks will see many more bills relating to health and medicine is a foregone conclusion.

It is certain, for instance, that Senator Wagner will shortly introduce a new bill to make effective a national health program on the scale of the bill he sponsored in the 76th Congress.

This bill, it will be remembered, provided for hospital construction, for compensation for disability wage losses, for expansion of maternal, infant, child health and welfare service, for general public helath services and general medical care. It may well gain impetus, rather than lose it, by direct link with the national defense program.

Announcement has been made, too, of a forthcoming bill to finance health care for every worker in defense industries. It is estimated that the plan would embrace at the start about 10,000,000 persons and the number of beneficiaries will obviously grow to staggering proportions if a truly "all-out" defense program gets under way. It has been suggested by sponsors, that, while the government would pay the bills, the medical care would "probably be rendered by private practitioners so as to avoid any controversy over 'socialized medicine.'"

As this issue goes to press, it is announced that the President will be ready shortly to propose a complete internal defense program for the United States. That program will undoubtedly cover the health of the people as an important adjunct to defense. It is likely to include new recommendations for medical services but physicians have the President's word for it, given in a preëlection speech, that such recommendations will not destroy the independence of the medical profession nor the quality of service they offer to the American people.

"SCHEMING ENTERPRISE"

From the *Washington Post,* February 7, 1941, by Gerald G. Gross, staff correspondent:

Coolly discussing Group Health Association and flinging the remains at prosecution counsel, William E. Leahy yesterday depicted the Federal employes' medical coöperative as a scheming, commercial enterprise which aimed to destroy organized medicine.

The Washington attorney's day in court was one such as law students dream of and their professors set up as models. For two and three-quarter hours, interrupted only by a five-minute recess, Leahy stood before the jury and worked on GHA.

The 20 doctors whom he is defending against the Government's charges of monopolistic practices might have called Leahy's opening statement to the jury an exploratory operation, a self-explaining type of surgery.

His scalpel a strong, unhesitating voice that never faltered during the lengthy speech, Leahy's incisive thrusts laid bare—according to his interpretation to the jury—a corporate body conceived with questionable motives, organized by "haughty and arrogant" men and dedicated to destruction of the hallowed traditions of the medical profession . . .

Speaking extemporaneously and without a note, eschewing a speaker's stand on which he might have leaned to rest his short, stocky frame, the defense lawyer systematically exposed, piece by piece, the alleged frailties of GHA which constitute the framework of the doctors' case of having been impelled in the public interest to challenge the coöperative.

He described Group Health Association, which was launched here in 1937 to furnish medical care on a prepayment basis, as "one of the most carefully conceived schemes ever put in operation," whose objective was to foist a socio-economic experiment upon the District . . .

He described Dr. Raymond E. Selders, a former medical director of GHA, as a doctor to whom local hospitals denied operating privileges because "the ink wasn't dry on his license to practice surgery when he applied" . . .

Leahy charged that GHA today offers little to subscribers and that it is doing 'practically nothing' for HOLC employes, for whom it was originally intended.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. DuBois, M.D., Secretary

Minneapolis Physician Pleads Guilty to Criminal Abortion

Re: State of Minnesota vs. Samuel R. Fraker.

On February 21, 1941, Dr. Samuel R. Fraker, 70 years of age, entered a plea of guilty in the District Court of Hennepin County, to an information charging him with the crime of abortion. Following a statement of the facts to the Court by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners. Dr. Fraker was sentenced to a term of not to exceed 4 years in the State Prison at Stillwater, which sentence was suspended upon Dr. Fraker's plea that he was suffering from pernicious anemia, and that he desired an opportunity to live with his daughter in Los Angeles, California. Dr. Fraker's plea was granted by Judge Arthur W. Selover, and the sentence was suspended for a period of 3 years.

Dr. Fraker was arrested on February 11, 1941, following a joint investigation by the Minnesota State Board of Medical Examiners and the Women's Bureau of the Minneapolis Police Department, of the facts concerning the abortion of a 17-year-old Minneapolis girl. At the time of his arrest, Dr. Fraker was maintaining an office at 315-316 Masonic Temple Building, Minneapolis, notwithstanding the fact that on November 4, 1938, his license to practice medicine was suspended for a period of 3 years for immoral, dishonorable and unprofessional conduct growing out of a previous criminal abortion. After Dr. Fraker had been sentenced by Judge Selover he was served with a citation requiring him to show cause why his license as a physician and surgeon should not be permanently revoked. Dr. Fraker was paid $50.00 for his services in performing the criminal abortion.

The Minnesota State Board of Medical Examiners fully approves of the disposition of the case as made by Judge Selover. Dr. Fraker's record discloses that it is futile to keep him out of the abortion racket as long as he remains in Minneapolis. Only two alternatives were available, one, to ask the Court to place Dr. Fraker in prison, and the other to accede to his request for a chance to live with his daughter, particularly in view of the condition of his health and age.

Unlicensed Healer Sentenced to Two to Twenty Years for Grand Larceny

Re: State of Minnesota vs. Mels White, alias Jackson Barnett, alias J. M. W. Barnett, alias Marion Royke, alias Marion Roller, alias Mariano Reyes.

The Minnesota State Board of Medical Examiners is pleased to be able to announce to the medical profession that following some splendid work by L. L. Roerkohl, County Attorney of Houston County, Minnesota, and Sheriff George V. Kelly of the same County, the above named defendant was sentenced on November 19, 1940, by Judge Vernon Gates of Rochester, Minnesota, to a term of 2 to 20 years in the Minnesota State Prison following White's conviction of the crime of grand larceny in the first degree.

County Attorney Roerkohl and Sheriff Kelly discovered that White had obtained $1,400.00 from a resident of Houston County by fraudulently mis-representing that White owned valuable oil lands in Oklahoma and that he needed money to finish drilling for oil. White also fraudulently misrepresented himself as an heir of the late Jackson Barnett, millionaire Oklahoma Indian. Notwithstanding the fact that the crime was committed in May 1939, and was not reported to the County Attorney or the Sheriff of Houston County, until the summer of 1940, Mr. Roerkohl and Mr. Kelly diligently pursued the matter, with the result that White was arrested and convicted by a jury of the crime of grand larceny. Due to the fact that White had been previously convicted of a felony, his sentence was doubled, which should eliminate him from the field of illegal medical practitioners for some time.

According to the records of the Medical Board, White came to Minnesota in the fall of 1934, and located at Winona. Following an investigation made by the Board, White entered a plea of guilty on May 8, 1935, to a charge of practicing healing without a Basic Science Certificate, and was sentenced to pay a fine of $200.00 or serve 2 months in the Winona County Jail. White served the jail sentence rather than pay the fine. In 1936, White was again arrested for practicing healing without a Basic Science Certificate and on October 8, 1936, entered a plea of guilty in the District Court at Rochester, Minnesota, where he was sentenced to a term of one year in the Olmsted County Jail. White's previous record shows that in 1917, he was convicted of carrying concealed weapons in the State of Indiana, and sentenced to serve 110 days at the Indiana State Farm at Green Castle, Indiana. Under the name of Marion Roller, White was convicted at Hudson, Wisconsin, in April 1926, of carnal knowledge, for which he served 7 years, 2 months and 6 days in the Wisconsin State Prison. In 1934, he pleaded guilty at Janesville, Wisconsin, to 2 charges of practicing healing without a Basic Science Certificate. While under arrest in the last case in Caledonia, it was learned that White had obtained $60.00 from a resident of Houston County, for herbs. It was also learned that he obtained $24.00 from a young lady in Houston County for herbs, which he did not deliver.

County Attorney Roerkohl and Sheriff Kelly deserve the highest commendation from the medical profession, as well as the general public, for their fine piece of work in putting out of circulation, one of the most persistent quacks ever to operate in this state. White's long criminal record proves that he has absolutely no respect for any of the laws and that he has made his living for a great number of years by imposing upon the public. We believe it is also a tribute to the Courts that Judge Gates imposed the maximum sentence.

HEALTH REPORT ON UNITED STATES TROOPS

The *Monthly Health Review* for troops in the United States, issued by the Surgeon General's Office, Washington, D. C. for the four weeks ended October 26, 1940, shows that the general admission rate for these troops was 740 per thousand as compared to 566 for the previous month, communicable diseases having been largely responsible for the increase. The rate for the respiratory group of diseases rose to 212.2 from 114.1 for September. Venereal diseases showed a slight decline to 39.1 from 44 for the previous month, being still well above the rate for the same period in the previous year. Two cases of typhoid were reported during the month, one in the Seventh Corps Area and one in the Eighth Corps Area; there was one case of typhus fever in the Fourth Corps Area and one of malta fever in the Ninth Corps Area. The rate for injuries showed an increase over that for September, 119 as compared to 87. The noneffective rate remained low, 21.7. The death rate was 2.61 per thousand. Of the seventy-nine deaths, four were due to adenocarcinoma, one to meningitis, three to tuberculosis, one to pneumonia, two to appendicitis, twenty-three to automobile accidents, twelve to airplane accidents, three to motorcycle accidents, six to suicide, three to homicide and two to drowning.

Dr. and Mrs. Harvey Hatch of Minneapolis are the parents of a son, born February 7.

* * *

Dr. W. W. Moir, Jr., is now in service and is at present stationed at Fort Wayne, Wyoming.

* * *

Dr. S. Marx White of Minneapolis was reëlected president of the Council of Social Agencies for a third term at the twenty-fifth annual election last month.

* * *

Dr. and Mrs. D. Kalinoff and daughter, Helen, are enjoying a vacation in the South, with Biloxi, Mississippi, as their headquarters.

* * *

New president of the Blackduck Golf Club at Blackduck, Minnesota, is Dr. Harry A. Palmer, who was elected at the annual meeting in January.

* * *

A postgraduate course in gastro-enterology was conducted for members of the American College of Physicians at the Mayo Clinic in Rochester, February 10 to 22, under the direction of Dr. Edgar V. Allen.

* * *

Dr. Richard M. Hewitt of Rochester attended a meeting of the Committee on Information, Division of Medical Sciences, National Research Council in Washington, D. C., February 10.

* * *

Fire, starting in an elevator shaft in the basement, recently destroyed Hall's Hospital in Little Falls. There were no patients in the three-story frame structure, which was also the residence of Dr. Elmer E. Hall.

* * *

Dr. William T. Peyton, head of the division of neurosurgery at the University of Minnesota Medical School, will leave about the middle of March on a six-weeks' clinical trip in the East.

* * *

Dr. O. M. Sanderson of Currie took over the office practice of Dr. Walter Henry Valentine of Tracy for two weeks last month, while Dr. Valentine was on vacation.

* * *

Dr. I. H. Kiesling, who has been located in Nashwauk for twenty years, is now a member of the Rood Hospital staff in Coleraine. Dr. Kiesling replaces Dr. J. A. Williams who has located in Hibbing.

* * *

Dr. T. E. Eyres of Pequot is remodeling and enlarging his office-and-residence. His offices will occupy the entire ground floor, while the second floor will be given over to living quarters.

* * *

Dr. C. A. Van Slyke was elected a new member of the board of trustees of the Swift County Hospital Association at the group's annual meeting held in Benson, Minnesota.

Dr. Lawrence F. Richdorf of Minneapolis, who suffered a shoulder fracture, January 12, when he slipped on the ice, is back at his office after spending three weeks in the hospital.

* * *

When the Goodhue and Wabasha County Medical Societies conducted a joint meeting in Red Wing, January 30, Drs. E. N. Cook, E. V. Allen and L. A. Brunsting of Rochester were speakers.

* * *

With the installation of new x-ray equipment, Drs. J. L. McLeod, J. C. Feuling, and J. O. Meyer enlarged their offices in Bovey. The rooms were also redecorated, and made sound-proof.

* * *

Dr. A. R. Ellingson of Detroit Lakes left February 24 for New Orleans, Louisiana, where he is taking a month's course in cystoscopy and x-ray diagnosis at Tulane University Medical School. Mrs. Ellingson accompanied him there.

* * *

Dr. Linus Leitschuh, who has been practicing medicine at Red Lake Falls in partnership with Dr. J. A. Roy, has disposed of his interests to Dr. Frank Petkevitch. Dr. Leitschuh has been called to service in the army.

* * *

Dr. George Friedell, formerly of Russell, Minnesota, has opened offices in Ivanhoe, having purchased the building and equipment of Dr. Alvin Erickson there. Dr. Erickson has been ordered to active service in the United States Army.

* * *

Dr. Stephen Baxter of Minneapolis has been reelected president of the Hennepin County Tuberculosis Association. Dr. W. H. Aurand was elected first vice president, and Dr. Russell Morse was named to the board.

* * *

Dr. and Mrs. E. J. Kepler and Dr. and Mrs. M. N. Walsh of Rochester left February 17 for Montevideo, Uruguay, where Dr. Kepler and Dr. Walsh will attend the second Pan-American Congress of Endocrinology. They made the trip by plane.

* * *

Dr. Janet Sutton, a graduate of the University of Minnesota Medical School, Class of 1940, has become associated with the Itasca Clinic of Grand Rapids-Bovey. She is the first woman physician to locate in Itasca County.

* * *

Two more physicians have been added to the staff of the Hastings State Hospital in Hastings. Dr. R. G. Barnes, an associate of Dr. R. C. Radabaugh in Hastings for the past year, has been named part-time physician on the staff, while Dr. Radabaugh has been named consulting surgeon.

Dr. Carl Eggers, head of the tumor clinic of the Post-Graduate Hospital in New York City, addressed members of the Minneapolis Surgical Society, February 6, at the organization's nineteenth annual foundation dinner held in the Minneapolis club. Dr. James A. Johnson, president of the society, presided.

* * *

Dr. Edgar S. Gordon, associate in medicine and instructor in physiological chemistry at the University of Wisconsin, Madison, was guest member of the faculty for the Continuation Course in Dietetics held February 20, 21 and 22 at the University of Minnesota Center for Continuation Study.

* * *

Two physicians are members of the state legislature. They are Dr. Reuben F. Erickson of Minneapolis, member of the House of Representatives from the Thirty-sixth District, south half; and Dr. Clifford I. Oliver of Graceville, senator from the Forty-eighth District.

* * *

Dr. Isadore Snapper, head of the department of medicine of Peiping Medical College at Peking, China, was a guest of Dr. Irvine McQuarrie of Minneapolis for a few days last month while visiting the University of Minnesota Medical School. Dr. McQuarrie was visiting professor at Peiping Medical College last year.

* * *

Dr. William A. Lange, plastic surgeon in Detroit, Michigan, and a graduate of the University of Minnesota Medical School in 1934, married Mrs. Annie Laurine Dodge in Champaign, Illinois, January 30. His bride is the widow of Daniel Dodge. Dr. Lange is a native of Lake City, Minnesota.

* * *

Dr. Gilbert J. Thomas was elected president of the staff of the Eitel Hospital in Minneapolis at a recent meeting. He succeeds Dr. A. C. Strachauer. Other officers are Dr. A. H. McFarland, assistant chief of staff, succeeding Dr. Walter Ude, and Dr. C. N. Borman, secretary, succeeding Dr. Theodore Stebbins.

* * *

Dr. Henry Silver of Willmar has purchased the practice of Dr. A. H. Borgerson in Sebeka. Dr. Borgerson recently moved to Long Prairie to take over the practice of Dr. M. G. Ericsson, who has moved to Cedar Falls, Iowa. Dr. Silver has been associated with the State Hospital at Willmar.

* * *

Dr. D. W. Pollard, who was recently named permanent superintendent of General Hospital in Minneapolis, has also been named to the position of Minneapolis city physician. In that capacity he will be the examining officer for all city departments and employes whose physical condition may affect their employment.

* * *

Drs. R. H. Creighton and E. C. Andreassen of Minneapolis, who will leave soon for Camp Claiborne, Louisiana, for service with the United States Army, were honored February 20 at a going-away dinner given at the Minneapolis Athletic Club by a group of their associates in the Medical Arts Building.

The Registry of Medical Technologists of the American Society of Clinical Pathologists has moved from Denver, Colorado, to Muncie, Indiana. Since its founding in 1928, Dr. Philip Hillkowitz has been chairman and Mrs. Anna R. Scott, registrar. Dr. Lall G. Montgomery, pathologist of the Ball Memorial Hospital, Muncie, is the newly appointed chairman of the Registry and Miss Carlita R. Swenson, formerly associated with the United States Pharmacopœia of Philadelphia, is the newly appointed registrar with headquarters at Muncie.

* * *

Two Minnesota men are among the ninety-four navy medical officers in the country whose promotions in ranks were approved recently by President Roosevelt. They are Dr. Harry J. Scholtes of Wabasha at Brooklyn, from lieutenant commander to commander; and Dr. Louis H. Roddis of Saint Paul at San Diego, from commander to captain.

* * *

Dr. Walter M. Boothby was in New York City, January 29, to address the ninth annual meeting of the Institute of Aeronautical Sciences on the subject, "High Altitude Flying: Prevention of Anoxemia and Aeroembolism." The article was written in collaboration with Dr. William R. Lovelace. He also attended a seminar on aviation medicine at Yale University in New Haven, Connecticut.

* * *

Dr. Chester A. Stewart of Minneapolis, clinical professor at the University of Minnesota Medical School, has been appointed director of the pediatrics department of the Louisiana State University Medical School in New Orleans. He will go to New Orleans next summer to assume his new post.

Dr. Stewart is a former president of the Hennepin County Medical Society.

* * *

Dr. William R. Lovelace of Rochester addressed a Postgraduate Course in Aviation Medicine at George Washington University School of Medicine in Washington, D. C., early in February. His subjects were: "Physiologic Effects of High Altitude Flying and Rapid Changes in Barometric Pressure," and "Transport of Surgical Patients in Airplane Ambulances; Indications and Hazards."

Dr. Lovelace was honored recently by the Rochester Junior Chamber of Commerce, being given the distinguished service award.

* * *

Alpha Epsilon Iota, honorary and professional sorority for women in medicine at the University of Minnesota, held its annual Founders' Day dinner in the Curtis Hotel in Minneapolis, February 22.

Guest speaker was Dr. Betty Nilsson, a graduate of the University of Illinois and head of the Rajahmundry Hospital in India, who talked on "Women in Medicine in India." Dr. Ruth Boynton was toastmaster.

* * *

Dr. Charles T. Bergen of Blue Earth has taken over the practice of Dr. H. W. Sybilrud of Bricelyn during the latter's service in the United States Navy. Dr.

Sybilrud has reported for duty at San Diego as lieutenant commander of the United States Naval Reserve Corps in the Second Marine Brigade.

A graduate of the University of Minnesota Medical School, Dr. Bergen has practiced at Northwood, Iowa, and at Blue Earth, Minnesota.

* * *

Dr. C. W. Mayo of Rochester was in Wheeling, West Virginia, February 14, to address a meeting of the Ohio County Medical Society on the subject, "Combined Abdominal Perineal Resection." From Wheeling he went to Washington, D. C., to speak at the George Washington University School of Medicine.

He also presented a paper, February 17, at a medical meeting in Newport News, Virginia. His paper was entitled, "Malignancy of the Colon."

* * *

Dr. Emil D. W. Hauser, assistant professor of bone and joint surgery at Northwestern University, addressed the Hennepin County Medical Society, February 3, on "Common Disorders of the Foot Due to Functional Decompensation."

A graduate of the University of Minnesota, Dr. Hauser obtained his Master of Science in orthopedic surgery as a fellow in the Mayo Foundation in 1927, and since that time has lived in Chicago.

* * *

Guest faculty member for the Continuation Course in the Anemias, March 3, 4 and 5, at the University of Minnesota Center for Continuation Study was Dr. William B. Castle, professor of medicine at Harvard Medical School in Boston.

Enrollment was limited to those with special training in internal medicine. The anemias were discussed from the laboratory, experimental and clinical viewpoints.

Dr. Castle also addressed a meeting of the Minnesota Pathological Society, on the University campus, March 4.

* * *

Dr. John P. Hawkinson of Crosby was one of seven fishermen stranded in Minnesota's north woods early last month, when their plane was disabled. The party was rescued by William Leithold, Ely mercy flier, who searched for them by starlight. The party had flown to Lake Gabimichigami, sixty miles east of Ely, to fish. As they prepared to take off on the return trip, one of the plane's skis broke through the ice.

Dr. Hawkinson is mayor of Crosby, and is the newly elected president of the Upper Mississippi Medical Society.

* * *

Medical reserve corps officers who had been ordered to active duty and whose orders have been revoked include:

Dr. George Stanford Atkinson, White Earth, first lieutenant, who had been ordered to Fort Snelling, Minnesota.

Dr. Leo V. James Conlin, Saint Paul, first lieutenant, who had been ordered to Carlisle Barracks, Pennsylvania.

Dr. Kinsey MacLeod Simonton, Rochester, first lieutenant; Dr. Carleton S. Strathern, Saint Peter, first lieutenant; Dr. Alfred Uihlein, Rochester, first lieutenant, and Dr. Louis Dysart Vaugh, Rochester, first lieutenant, all of whom had been ordered to Camp Grant, Illinois.

Dr. C. C. Clay of Minneapolis was in charge of arrangements for a McGill University dinner at the Leamington Hotel, February 13, at which Dr. F. Cyril James, principal of McGill University, Montreal, was guest of honor.

Guests included the following physicians who are graduates of the university: Drs. Peter Ward, A. R. Hall, Alexander Stewart, A. R. Colvin, E. L. Kannary and J. F. Hammond of Saint Paul; Drs. G. L. Evans, Edmund Murphy and George Kennedy of Minneapolis.

Other guests were Drs. John McKelvey, C. W. del Plaine and John Korchik of Minneapolis.

* * *

Dr. Julian F. DuBois of Sauk Center, secretary of the Minnesota Board of Medical Examiners, Saint Paul, and F. Manley Brist, attorney for the Board, presented a paper, "Medical Laws and Their Enforcement," at a meeting of The Federation of State Medical Boards held in Chicago in conjunction with the thirty-seventh Annual Congress on Medical Education and Licensure, February 17 and 18.

Also on the program for the Congress was Col. Leonard G. Rowntree, who was recently appointed Chief of the Medical Division of the Selective Service System, Washington, D. C. Colonel Rowntree was for many years professor of medicine at the University of Minnesota Medical School and chief of the medical division of the Mayo Foundation.

* * *

Speakers at the regional meeting of the Women's Field Army of the American Society for the Control of Cancer, held in Rochester, February 6 and 7, included besides Mayo Clinic staff members:

Dr. A. J. Chesley, secretary of the Minnesota State Board of Health; Dr. William A. O'Brien, president of the Minnesota Society for the Control of Cancer, who gave the principal address at the banquet, "Why Lay Education is Necessary in the Cancer Control Program;" Dr. Gaylord W. Anderson, head of the department of preventive medicine and public health at the University of Minnesota.

Also in attendance were Dr. Max W. Alberts, vice president of the Minnesota society, and Dr. B. J. Branton, president of the Minnesota State Medical Association.

* * *

The value of fraternity life to a medical student was stressed at the forty-third annual Founders' Day dinner, February 18, of Psi chapter, Alpha Kappa Kappa medical fraternity, in the Town and Country Club in Saint Paul.

Principal speaker was Dr. William Mann, professor at Northwestern University and grand president of the fraternity. Other speakers included Dr. Burton J. Branton, president of the Minnesota Medical Association; Dr. Harry G. Irvine, associate professor of dermatology at the University of Minnesota Medical School; and J. Gordon Bateman, president of the chapter. Dr. Irvine presented the organization with a photostatic copy of a picture of the chapter's charter members taken in 1896.

Dr. Max Alberts was toastmaster.

Dr. A. V. Stoesser, associate professor of pediatrics at the University of Minnesota Medical School, addressed a meeting of the Omaha County Medical Society in Omaha, February 11.

Dr. Stoesser also was in South Dakota about the middle of February to address two educational institutes on the medical care of the premature infant. The institutes for physicians and nurses, conducted by the South Dakota State Department of Health, were held in Huron, February 17, and in Rapid City, February 19. Miss Gertrude Carlsrud of the Minnesota State Department of Health, nursing instructor in premature infant care, also participated in the institutes.

* * *

Dr. Henry E. Michelson of Minneapolis will present a paper, May 20, on diseases of the skin, at the annual meeting of the North Dakota State Medical Association to be held in Grand Forks, May 18-21. He will also lead a round-table discussion at a noon luncheon, May 20.

Dr. Michelson has also accepted invitations to address the South Dakota State Medical Association at its meeting in Mitchell, May 19 and 20, and the Nebraska State Medical Association, which will meet in Lincoln, May 5 to 8.

Next November he will go to Oklahoma City to address the Oklahoma City Clinical Conference, November 3-6, 1941, as one of sixteen guest speakers. Approximately 650 doctors from Oklahoma, Kansas, Missouri, Arkansas, Colorado, Texas and New Mexico will participate in this meeting.

* * *

Three Minnesotans participated in the fifteenth annual meeting of the National Conference on Medical Service (formerly the Northwest Regional Conference) in Chicago, February 16.

They were Dr. William A. O'Brien of Minneapolis, director of postgraduate medical education at the University of Minnesota Medical School; Walter F. Finke, director of the Minnesota Division of Social Welfare of the Department of Social Security, Saint Paul; and Dr. Alfred W. Adson of Rochester, chairman of the Medical Advisory Committee to the Minnesota Division of Social Welfare.

Dr. O'Brien participated in a discussion of state medical societies' postgraduate programs and spoke on the subject, "As Carried On in Minnesota; a Coöperative Program."

Mr. Finke and Dr. Adson presented a paper on "Minnesota's Plan for the Care of the Medically Indigent."

* * *

Elizabeth Kenny, Australian nurse who has demonstrated her method of treating infantile paralysis at the Minneapolis General Hospital for the past nine months, sailed recently for her home in Brisbane to assemble a technical staff preparatory to establishment of treatment facilities at the University Hospitals. She will return to Minneapolis in May.

For the past nine months she has demonstrated her method of treatment at General Hospital, working under the supervision of Dr. Wallace Cole, head of the department of orthopedic surgery at the University and now director of the American Hospital in Britain; Dr. John H. Moe, chief of orthopedics at General Hospital; Dr. Miland E. Knapp, chief of physiotherapy at General Hospital, and Dr. John F. Pohl, attending orthopedic surgeon at General Hospital. Her work is partially supported by the National Foundation for Infantile Paralysis.

* * *

Among the twenty-two new Fellows in the Mayo Foundation at Rochester are Dr. John H. Rosenow, son of Dr. and Mrs. E. C. Rosenow of Rochester, who is a graduate of Harvard University Medical School, and Dr. Delmar R. Gillespie of Lakota, North Dakota, who received his M.D. from the University of Minnesota Medical School.

Others are: Dr. Guy W. Daughtery of Fayetteville, West Virginia; Dr. Philip D. Gelbach, Evans City, Pennsylvania; Dr. Julian P. Levinson, Brownsville, Pennsylvania; Dr. Francis R. Manlove, Philadelphia; Dr. Gideon R. Wells, Chicago; Dr. C. Hal McCuistion, Austin, Texas; Dr. J. Wayne McFarland, Los Angeles; Dr. Edward E. Cannon, Chicago; Dr. Edward T. Clarke, Houston, Texas; Dr. Charles V. Demong, Syracuse; Dr. Charles H. Evans, Waddington, New York; Dr. A. Wesley Hildreth, Bay Shore, New York; Dr. Hiram D. Hilton, Lincoln, Nebraska; Dr. Spencer K. Phillips, Freeport, Illinois; Dr. Thomas S. Sexton, Sistersville, West Virginia; Dr. Frederick H. Smith, Ailsa Craig, Ontario; Dr. Henry R. Large, Cleveland; Dr. Samuel M. Brooks, St. Johnsbury, Vermont; Dr. Thomas N. Foster, San Jose, California; Dr. Gustav O. Kruger, Jr., of Washington, D. C.

Dr. Abel N. A. Canonicao, a Rockefeller Foundation Fellow, is working with Dr. F. C. Mann and his associates at the Institute for Experimental Medicine.

* * *

The following medical reserve corps officers have been ordered within the past few weeks to extended active duty:

Dr. Edwin Grimshaw Benjamin, Minneapolis, first lieutenant, to Fort Sam Houston, Texas.

Dr. Harold Clark Johnson, Thief River Falls, first lieutenant, to Fort Sam Houston, Texas.

Dr. Ralph Burnsell Kettlewell, Sauk Center, captain, to Fort Riley, Kansas.

Dr. Frank Lloyd Richardson, Minneapolis, first lieutenant, to Carlisle Barracks, Pennsylvania.

Dr. Byron Lee Gifford, Long Prairie, first lieutenant, to Camp Murray, Tacoma, Washington, and to Randolph Field, Texas, after which he will become flight surgeon with the air corps.

Dr. Henry Burton Grimes, Madelia, major, to Fort Ord, Presidio of Monterey, California.

Dr. John Kenneth Helferty, Tracy, first lieutenant, to Fort Ord, California.

Dr. Jules Owens Meyer, Grand Rapids, first lieutenant, to Fort Ord, Presidio of Monterey, California.

Dr. Joseph Herman Sagi, Minneapolis, first lieutenant, to Fort Lewis, Washington.

Dr. Rosel Theodore Seashore, Minneapolis, first lieutenant, to Fort Ord, Presidio of Monterey, California.

Dr. Donald Edward Stewart, Grand Rapids, first lieutenant to Fort Lewis, Washington.

Dr. David Albert Burlingame, Minneapolis, first lieutenant, to William Beaumont General Hospital, El Paso, Texas.

Dr. Raymond Paul Hawkinson, Robbinsdale, captain, to Fort Des Moines, Iowa.

Dr. Charles King Holmes, Minneapolis, lieutenant colonel, Minneapolis to Hot Springs, Arkansas.

Dr. Abraham Benjamin Rosenfield, Hibbing, captain to Hot Springs, Arkansas.

Dr. Russell Olay Sather, Crookston, captain, to El Paso, Texas.

Dr. Jacob Allan Sheinkopf, Minneapolis, captain, to Hot Springs, Arkansas.

Also Dr. Andrew W. Shea, first lieutenant, Minneapolis; Dr. John Mendenhall Snyder, captain, Rochester; and Dr. Robert Woodruff, first lieutenant, Rochester.

In Memoriam

Edmund Levings Warren

Dr. E. L. Warren, eye, ear, nose and throat specialist of Saint Paul, died February 19, 1941, following a month's illness.

Dr. Warren was born June 26, 1884, in New York City, the son of Mr. and Mrs. Alvah H. Warren. He came to Saint Paul at an early age. He attended the Irving School and later Mechanic Arts and Central High Schools; he graduated from Central High School in 1904.

After two years of academic work at the University of Minnesota he took his medical course at the College of Physicians and Surgeons, Columbia University, graduating in 1910. His internship was taken at the New York City Hospital in 1911 and 1912 and post-graduate work at the Manhattan Eye, Ear and Throat Hospital, New York City.

Dr. Warren passed the state board examinations in New York, Washington and California and practiced in New York and Pasadena before locating in Saint Paul in 1914. He was a member of the executive committee of the Children's Hospital and a member of the staffs of Saint Luke's, Miller, Saint Joseph's and Gillette Hospitals.

An ardent hunter, fisherman and outdoor enthusiast, Dr. Warren periodically wrote articles which appeared in sporting magazines. One trip on horseback into the wilds of the Canadian Rockies after big game and another into the mountains of Idaho provided trophies for Dr. Warren and material for his pen.

Dr. Warren was a member of the Psi Upsilon Fraternity, the Ramsey County Medical Society, and the Minnesota State and American Medical Associations.

Dr. Warren is survived by his widow, Helen Powers Warren, two sisters, Mrs. M. S. Stringer, Saint Paul, and Mrs. R. Kingsland Hay, New York City, and a brother, A. H. Warren, of Pittsburgh, Pennsylvania.

Dr. Warren had the distinction of having had a tracheotomy performed on him for membranous croup in infancy by Dr. Jacoby of New York. He, himself, used to tell of performing an emergency tracheotomy with his pen knife on a fellow traveler on a train bound for the west before he had passed his state board examinations. The cap of his fountain pen was used for a tracheotomy tube.

Possessed of an unusual kindliness of heart, Dr. Warren was blessed with many close friends both within and outside the profession.

William David Beadie

Dr. William D. Beadie, formerly superintendent of Mineral Springs Sanatorium, Cannon Falls, Minnesota, died at Windom, Minnesota, on February 7, 1941.

Dr. Beadie was born in Toronto, Canada, on June 15, 1874. His parents were both natives of Scotland. When he was thirteen years of age he moved with his family to Lachine, a suburb of Montreal. He attended school there and took his medical course at McGill University, where he graduated in 1900.

After graduating from McGill University Medical School, Dr. Beadie came to Windom, Minnesota, where he practiced general medicine until 1910. In 1910 he moved to Saint Paul and practiced general medicine there until 1917. In 1917 he was made superintendent of Pokegama Sanatorium. In 1923 he took the position of superintendent at Mineral Springs Sanatorium. He held this position until he resigned on account of illness at the end of December, 1940. During his régime Mineral Springs grew from a two-county to an eight-county institution largely through his efforts.

In December Dr. and Mrs. Beadie moved to Windom to be with Mrs. Beadie's sister, Miss Margaret McGregor.

Dr. Beadie married Elizabeth McGregor of Windom, October 21, 1903. Mrs. Beadie and a son, William, of Saint Paul and two grandsons survive.

During his residence in Saint Paul Dr. Beadie was a member of the Ramsey County Medical Society and later became a member of the American Trudeau Society and the National Tuberculosis Association.

When Dr. Beadie was forced to retire as superintendent of Mineral Springs Sanatorium because of illness, the December issue of the *Sanscript,* the publication of the sanatorium, was devoted to his praise. This must have been a source of real satisfaction to him. Perhaps "perfect gentleman" best described Dr. Beadie in the eyes of his many friends.

John P. Hiebert

Dr. John P. Hiebert, Minneapolis, died October 11, 1940, at the University Hospital.

Dr. Hiebert was born at Mountain Lake, Minnesota, in 1876. He obtained his medical degree at Northwestern University Medical School in 1905, and began practice in Minneapolis in 1914. He was Chief of Staff at Asbury Hospital in 1938 and was a member of the Eitel, Abbott and Asbury Hospital staffs. He was active in practice until two weeks before his death.

Dr. Hiebert is survived by his wife, three brothers and four sisters.

MEDICAL BROADCAST FOR MARCH

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Professor of Preventive Medicine and Public Health, Medical School, University of Minnesota.

March 8—Records of Birth
March 15—Life's Increasing Span
March 22—Diseases of Middle Life
March 29—Orthodontia

DR. SCUDDER TO SPEAK AT ROCHESTER

Dr. John Scudder of the Columbia University College of Physicians and Surgeons in New York City, who will come to Minneapolis to address the regional meeting of the American College of Surgeons, March 10, 11 and 12, will also lecture in Rochester.

He will speak there, March 6, on the subject, "Blood Studies in Shock as a Guide to Therapy."

CLARENCE M. JACKSON LECTURE

The Clarence M. Jackson lectureship, established by Phi Beta Pi medical fraternity, will be delivered by Dr. Carl R. Moore, chairman of the department of zoölogy at the University of Chicago, March 19, at the University of Minnesota.

His subject will be "The Significance of Hormones in Embryonic Sex Differentiation."

JOHN PHILLIPS MEMORIAL AWARD, 1941

The Board of Regents of the American College of Physicians has awarded the 1941 John Phillips Memorial medal to Dr William Christopher Stadie, Associate Professor of Research Medicine at the University of Pennsylvania, for his contributions to the knowledge of anoxia, cyanosis and the physical chemistry of hemoglobin, and more especially for his recent studies on the subject of fat metabolism in diabetes mellitus.

The recipient will present the work mentioned at the next annual session of the college.

STATE MEETING

Surgery of trauma will be the general subject of an entire day's program to be presented in connection with the 88th Annual Meeting of the Minnesota State Medical Association, May 26, 27 and 28, at the Saint Paul Auditorium.

For this program, scheduled for Tuesday, May 27, surgeons of all Northwest railways will join with the Association, and several outstanding guest speakers have been invited to participate. The Great Northern Railway Association will hold its own annual sessions in Saint Paul on the day preceding so as to be present for this program.

Emphasis in selection of all subjects and speakers has been placed, according to the Committee on Scientific Assembly, on the special interests and needs of the general practitioner.

Round-table luncheons are being arranged for each day of the meeting and an Open House and "Gay Nineties" show will be held in the exhibit hall Monday night. Tuesday night will be devoted to the annual banquet of the Association.

Among distinguished visiting speakers already scheduled for the three-day meeting are Dr. Edward D. Churchill, John Homan, professor of surgery at Harvard, who will come under the sponsorship of the Saint Paul Clinical Club; Dr. H. H. Kessler of Newark, N. J., and Dr. Walter Simpson of Dayton, Ohio, who is sponsored by the Northern Minnesota Medical Association.

Physicians from all the Northwest states will be invited to attend the sessions.

CLINICAL RESEARCH CLUB

A new organization at the University of Minnesota Medical School is the Clinical Research Club, which will become affiliated with the newly organized American Federation for Clinical Research. An organization meeting of the federation, which is to be a society of young men and women interested in and carrying on clinical investigation, is to be held May 5 in Atlantic City, New Jersey.

Dr. John A. Layne is chairman of the University of Minnesota Club. Members of the advisory board are Dr. John Anderson, pediatrics; Dr. Clarence Dennis, surgery; Dr. Robert Hebbel, pathology.

Meetings will be held the first Monday of each month.

MINNESOTA DERMATOLOGICAL SOCIETY

The twenty-fifth anniversary of its founding was celebrated February 22 by the Minnesota Dermatological Society with a clinic at the University Hospitals in Minneapolis and a dinner at the Minneapolis Club. Members of the Chicago Dermatological Society were guests.

Honored at the dinner were founders of the organization, which is one of the older dermatological societies of the country. Founders include Drs. John Butler, Samuel E. Sweitzer and Clifton A. Boreen of Minneapolis; Drs. Charles D. Freeman, John M. Armstrong and Henry N. Klein of Saint Paul.

Speakers were Dr. Sweitzer, who presented the history of the organization; Dr. J. H. Mitchell of Chicago, who discussed the activities of the society's nearest

neighbor, the Chicago Dermatological Society; and Professor Morris Oppenheim of the University of Chicago, and formerly of Vienna. He discussed the old Vienna clinics.

The Minnesota Dermatological Society, which has had a big influence in the shaping of dermatological thought of this part of the country, is composed of members from the Twin Cities, Duluth, Rochester. The Society conducts monthly clinical sessions. A special meeting is held during the summer in Rochester, Duluth or Winnipeg.

Dr. Henry E. Michelson of Minneapolis and Dr. Francis W. Lynch of Saint Paul were in charge of arrangements for the twenty-fifth anniversary meeting.

DU BOIS ELECTED FEDERATION PRESIDENT

At the annual meeting of the Federation of State Medical Boards, held at Chicago on February 17 and 18, 1941, Dr. Julian F. Du Bois of Sauk Center, Minnesota, was unanimously chosen as president-elect of the Federation. Dr. Du Bois will succeed Dr. J. Earl McIntyre of Lansing, Michigan, president of the Federation during the present year.

All state medical examining boards are eligible for membership in the Federation, and at the present time, thirty-nine states are represented in its membership. The purpose of the Federation is to keep itself and its members informed concerning the medical and other healing art practice acts of the various states and of foreign countries. Consideration is given, from time to time, of suggestions made relating to medical education and licensure. It sponsors a program each year in which the various problems confronting the medical examining boards of the various states, are discussed. The guest speaker of the Federation banquet this year was Ray Lyman Wilbur, M.D., president of Stanford University and chairman of the Council on Medical Education and Hospitals of the American Medical Association. Dr. Wilbur will be remembered by many members of the medical profession as Secretary of the Interior in the Cabinet of former President Hoover.

The Minnesota State Board of Medical Examiners has been very active in the Federation since its organization twenty-seven years ago, and the selection of Dr. Du Bois, in addition to being a personal tribute to him, brings further honor to the medical profession of Minnesota and to the Minnesota State Board of Medical Examiners. Dr. Du Bois was first appointed a member of the Minnesota State Board of Medical Examiners by former Governor Theodore Christianson. In 1935 he was made secretary of the Board and he has acted in that capacity since that time.

BROWN-REDWOOD MEDICAL SOCIETY

Members of the Brown-Redwood Medical Society and the Women's Auxiliary held an annual dinner at Springfield, January 29.

Dr. H. Mortensbak of Hanska is president of the society. Other officers are Dr. E. J. Wohlrabe, Springfield, vice president, and Dr. O. B. Fesenmaier of New Ulm, secretary-treasurer.

FREEBORN COUNTY MEDICAL SOCIETY

Dr. A. Gullixson of Albert Lea was elected president of the Freeborn County Medical Society at its annual meeting, February 5, in Albert Lea. Other officers are: Dr. Paul Gamble, vice president; Dr. L. R. Prins, secretary; Dr. D. L. Donovan, treasurer.

SCOTT-CARVER MEDICAL SOCIETY

Dr. C. C. Chatterton of Saint Paul and Dr. Malvin Nydahl of Minneapolis addressed the Scott-Carver Medical Society, February 11. Dr. Chatterton spoke on "Fractures of the Elbow" and Dr. Nydahl explained the "Functions of the Crippled Children's Bureau."

Dr. Francis Lynch of Saint Paul addressed the society in December. His subject was "Treatment of Common Skin Disorders."

UPPER MISSISSIPPI MEDICAL SOCIETY

Dr. John P. Hawkinson of Crosby was elected president of the Upper Mississippi Medical Society at the organization's winter meeting. He succeeds Dr. Nesmith Nelson of Brainerd.

Other officers named are: Dr. R. A. Murray of Aitkin, first vice president; Dr. C. W. Vandersluis of Bemidji, second vice president. Dr. G. I. Badeaux of Brainerd was reëlected secretary-treasurer.

Dr. B. A. Smith of Crosby and Dr. Badeaux were selected delegates to the State Medical Association meeting, while Dr. A. M. Watson of Royalton, and Dr. John Thabes, Jr., of Brainerd were named alternates.

Dr. Smith was reëlected for a three-year term on the board of censors. Other board members are Dr. W. W. Will of Bertha and Dr. John Thabes, Sr., of Brainerd.

The spring meeting of the group will be held in Aitkin, the summer meeting in Bemidji, the fall session in Little Falls, the election meeting next year in Brainerd.

WASHINGTON COUNTY MEDICAL SOCIETY

The regular monthly meeting of the Washington County Medical Society was held on February 11 at the Stillwater Club rooms, Stillwater, Minnesota. Dr. John M. Culligan of Saint Paul, guest speaker, showed and interpreted slides of x-ray pictures of intravenous and retrograde pyelograms. Dr. D. A. Dukelow, Director of Public Health Education, State Board of Health, spoke about the packets sent by the Minnesota State Medical Association.

WOMAN'S AUXILIARY

Mrs. M. A. Nicholson, Duluth, Minnesota, *President*
Mrs. E. V. Goltz, 2259 Summit Avenue,
Saint Paul, *Publicity Chairman*

Headquarters for the Woman's Auxiliary at the annual meeting of the American Medical Association in Cleveland, June 2-6, 1941, will be the Hotel Carter. Reservations should be made with Dr. E. F. Kieger, Chairman Housing Committee, 1604 Terminal Towers Building, Cleveland, Ohio.

State Board Meeting

The mid-winter meeting of the State Auxiliary Board was held in Saint Paul, February 4, at the Commodore Hotel with Mrs. Harry Ghent, Saint Paul, as social chairman. A large group of members attended the business meeting which was held at 9:30 a. m., followed by luncheon at noon and an afternoon session. The state president, Mrs. M. A. Nicholson of Duluth, presided and heard reports from the various county presidents. Dr. William O'Brien spoke at the morning session on "The Control of Cancer." At the luncheon meeting, Mrs. Howard A. Overman of the state committee of the Women's Field Army for the Control of Cancer, also spoke on the subject. Plans for the annual state meeting to be held in Saint Paul in May were discussed and the following nominating committee was named: Mrs. E. M. Hammes, Mrs. Wm. Robert, Mrs. L. Dack, Mrs. A. C. Baker, and Mrs. H. P. Fischer.

Clay-Becker County

Newly elected officers of the Clay-Becker Medical Auxiliary include Mrs. O. O. Larson, Detroit Lakes president; Mrs. C. W. Simmison, Hawley, vice president; Mrs. L. H. Flancher, Lake Park, secretary-treasurer. The Auxiliary, which numbers twelve members, sponsored a sale of articles by the patients of Sand Beach Sanatorium, clearing $93.59. On January 24, Dr. Charles B. Craft talked to the P.T.A. on cancer, a meeting which was open to the public and sponsored by the Auxiliary.

Hennepin County

Members of the Hennepin County Auxiliary enjoyed colored movies of a trip to Guatemala which were shown by Mrs. Harvey Nelson at their recent meeting. Mrs. H. B. Sweetser was chairman for the tea which followed the program and Mrs. Martin Aune and Mrs. J. R. Peterson poured. Assisting members included Mrs. James Blake, Jr., Mrs. A. C. Kirkhoff, Mrs. Robert Quello and Mrs. R. F. McGandy.

A net amount of $1,203 was realized through the sale of articles made by patients at Glen Lake Sanatorium. The proceeds were turned over to the patients.

Mower County

Mrs. Paul Leck of Austin entertained the Mower County Auxiliary at a dessert luncheon January 28. Following the business session, Mrs. C. L. Sheedy read a paper pertaining to the future practice of medicine. A social hour at bridge followed. Mrs. J. E. Eckdale of Lyle, a prospective member, was a guest.

Red River Valley

The Red River Valley Auxiliary were guests of Mrs. W. E. Mercil the evening of December 3, following the dinner meeting of the Medical Society at which they were guests. There were fourteen members present including several out-of-town members. At the business meeting reports were received on the tuberculosis essay contest for which the auxiliary provides cash awards. Out-of-town guests included Mrs. D. V. Boardman, Mrs. E. Haugseth of Twin Valley and Mrs. W. H. Hollands of Fischer and Mrs. A. Shedlov of Fosston.

Rice County

Rice County Medical Auxiliary held a meeting January 16 at the home of Mrs. S. B. Haessly in Faribault. Miss Muriel Young, visiting nurse, was a guest. The afternoon was spent in knitting and sewing for the Rice County chapter of the Red Cross followed by tea and a social hour.

Upper Mississippi

Upper Mississippi Medical Auxiliary recently elected the following new officers: Mrs. A. E. Amundson, Little Falls, president; Mrs. H. W. Lee, Brainerd, president-elect; Mrs. J. P. Hawkins, Crosby, vice president; Mrs. Douglas Johnson, Little Falls, secretary. Mrs. Lee was reëlected treasurer and Mrs. George Halladay acting secretary for the remainder of this year. Following the business meeting held at the Ransford Hotel, a dinner was served for twenty-one. Mrs. Nesmith Nelson, retiring president, presided. After dinner two essays were read by the winners in the Tuberculosis Essay Contest.

PHYSICIANS WANTED FOR CCC DUTY

Physicians are needed for the medical service of the Civilian Conservation Corps. The initial salary is $3,200 per annum. No quarters for families are provided, and the physicians are required to pay for their food at camps. Temporary quarters for physicians are provided at the camps for a nominal fee. Physicians selected for this service are required to pay their own travel expenses to the headquarters of the district in which they are to be employed, where they are put on temporary duty for instructional purposes before being sent to camps. Travel expenses incurred in the transfer of physicians from the district headquarters to camps or in transfer from one camp to another are paid by the Government.

The principal duties at camps consist of the medical care of the enrollees and the practice of preventive medicine. To be eligible for this service, the physician must be a citizen of the United States, a graduate of an accredited medical school authorized to confer the degree of doctor of medicine, licensed to practice medicine, and physically able to perform the duties involved. Physicians sixty years of age or over will not be employed.

All physicians interested in this type of service are requested to submit their applications to the Office of the Surgeon, Headquarters Seventh Corps Area, Federal Building, Omaha, Nebraska, giving date on which available and preference of assignment in the following states: Minnesota, North Dakota, South Dakota, Iowa, Nebraska, Missouri, Kansas, and Arkansas.

It is requested that young physicians not now listed in the American Medical Directory be informed of this service.

TRANSACTIONS OF THE MINNEAPOLIS SURGICAL SOCIETY

Stated Meeting, Thursday, October 3, 1940

PRESIDENT JAMES A. JOHNSON, M.D., in the chair

SECRETARY R. F. McGANDY, M.D.

INGUINAL HERNIA FOLLOWING ABDOMINAL SURGERY*

MARTIN NORLAND, M.D.
Minneapolis

UNSATISFACTORY RESULTS FROM THE INJECTION TREATMENT OF HERNIAS COMPARED TO SURGICAL REPAIR*

HARVEY NELSON, M.D.
Minneapolis

COMPLICATIONS ASSOCIATED WITH THE TREATMENT OF HERNIA†

Injection versus Operative Treatment

CARL O. RICE, M.D.
Minneapolis

It has been difficult to evaluate the benefits of the injection treatment of hernia as compared with the surgical treatment because, there is no doubt, the two series of cases are different, or if they are not, they should be. It is true that many cases which are suitable for operation are not suitable for injection. For that reason, among others, many of the opponents of the injection treatment prefer to dismiss injection treatment by merely stating that, if it is of no value for the cases that cannot be operated, then it has no value at all. Such a contention, of course, is erroneous.

By presenting the complications and sequellæ which occur with each method of treatment, I hope to show that the injection treatment of hernia should have a place in our surgical armamentarium.

Of 300 patients who consulted me for examination and advice, 215 (71.6 per cent) were advised that injection would be satisfactory. One hundred sixty-eight (56 per cent of the total) returned and received a full course of treatments, namely, were treated until cured or until they were convinced they could not be cured.

All complications and sequellæ were carefully recorded in these cases and are listed in the accompanying table.

COMPLICATIONS AND SEQUELLÆ FROM INJECTION TREATMENT

	Cases	Per Cent	
None	126	75	
Sterile Abscess	4	2.3	
Allergic Reactions	4	2.3	8.3
Anaphylactic—2			
Urticarial—2			
Vein Punctured (No hematoma)	6	3.7	
Induration of Cord	10	5.9	
Soreness	16	9.5	
Omentum in Sac	1	.7	
Deaths	None	None	

It is seen from these figures that in 8.3 per cent of the cases an undesirable and potentially dangerous reaction occurred. The other sequellæ were of no serious consequence and did not add to the risk of treatment.

Induration of the cord indicates an excessive reaction to the injection fluid, but usually assures a cure.

Soreness as experienced in 9.5 per cent of the cases was of no serious consequence, and probably indicates only a lesser degree of tolerance to pain than most individuals experience.

In the one case in which the omentum could not be reduced from the hernial sac after injections had been started it became necessary to discontinue the treatment. This in no way added to the risk of treatment, nor to the difficulty of a subsequent operation.

The details of the end-result in these cases will not be dealt with in this paper, but I can definitely state that seventeen (15 per cent) of these failed to obtain a cure. The causes of failure were as follows:

Obesity	8
(Six of these had been advised against injection, but decided to try it anyway.)	
Postoperative Cases	4
(Three had been advised against treatment.)	
Omentum in Sac	1
Became Allergic	2
Lack of Coöperation	2

Strangely, fourteen physicians (9 per cent) were included in this group of 168 patients. Five were advised against the treatment, but preferred to try it. There was failure in three of these.

This series may be compared with a somewhat larger group of 868 patients who were seen at the Minneapolis General Hospital, upon whom 555 operations were performed. The following complications occurred.

COMPLICATIONS FOLLOWING OPERATION

	Cases	Per Cent	
Primary Healing	389	70	
Abscess	3	.5	27.3
Stitch Infection	5	.9	
Wound Break Down	19	3.4	
Serous Exudate	64	11.4	
Wound Infection	31	5.4	
Bloody Exudate	22	4.1	
Hematoma	11	2.0	
Induration of Wound	6	1.1	
Ecchymosis	2	.4	
Deahts	5	.9	

*Presented at the meeting but not submitted for publication.

†Assistance in the preparations of these materials was furnished by the personnel of Work Projects Administration, Official Project No. 65-1-71-140, Sub-project No. 361.

It is true that most of these 555 operations were performed by house physicians whose experience is not as great as that of the staff surgeons, but the fact that 27.3 per cent of the operated cases developed undesirable local wound reactions is in itself quite alarming. The remaining 1.5 per cent of local wound sequellæ were not particularly serious.

In addition to these local complications a certain number of patients also developed systemic complications which probably would not have occurred had the patient not been operated upon. These are as follows:

SYSTEMIC COMPLICATIONS FOLLOWING OPERATION

	Cases	Per cent
Pneumonia	20	3.6
Bronchitis	12	2.1
Cough	31	5.6
Thrombophlebitis	1	.18
Embolism	4	.7
Empyema	5	.8
Intestinal Obstruction or Paralytic Illeus	32	5.7
Pulmonary Edema	9	1.5
Shock	6	.9
No systemic complications	435	78

Though I cannot give in this preliminary report the figures relative to the seriousness of the condition of these patients before operation, I do not wish to leave the impression that all of the hernias were uncomplicated. Neither were all these patients poor surgical risks. A more detailed report will be made later. I wish only to call attention to the fact that hernia surgery is not as simple as we are sometimes led to believe.

I do desire to emphasize that the incidence of complications and sequellæ following operations for hernia are not less than those following injection. It seems that it is justifiable to conclude that with proper selection, the injection treatment of hernia does have a place in our surgical armamentarium.

Discussion

Dr. Martin Nordland: Is there any percentage of sterility following injection treatment?

Dr. Carl O. Rice: As far as it has been possible to determine, there have been no cases of sterility nor atrophy of the testicle resulting from the injection treatment of hernia. Dr. Charles Rea has made a study of this, and was unable to find a higher incidence of aspermia in bilaterally injected individuals than in an uninjected group of individuals. We all have no doubt seen cases of testicular atrophy following herniaplasty. I have never observed one following the injection treatment for hernia.

Dr. James M. Hayes: Can injection treatment be used in postoperative hernia or with old men who have weakened abdominal walls?

Dr. Rice: I do not choose to treat postoperative hernias. Sometimes patients insist that I try, even though I advise against it. If such is the case I see no harm in trying. In a few instances I have been successful, though I do not recommend it. The sooner we learn the contraindications for injection and the more accurately we adhere to them, the quicker we will be able to place the injection treatment in the catagory to which it belongs. A relaxed abdominal wall in an old patient is not in itself a contra-indication for the injection treatment.

FIBROMA OF THE VAGINA

Report of Case

Ivar Sivertsen, M.D.

Minneapolis

Dr. George Ernest Herman states in his book on "Diseases of Women" that fibroids of the vagina are so rare that no one can describe them from actual personal experience. He quotes John Phillips: "that an account of them must be based on collections of them in books and case reports."

William Esterly Ashton, in his textbook on "Practice of Gynecology" gives a very good description of the condition but states that the cause is unknown.

Dr. Frank Lynch in his monograph "Pelvic Neoplasms," states that fibromyoma of the vagina rarely originates in the vagina, and that up to 1886 only six cases were collected; and quotes Smith, in 1902, that 100 cases had been collected; Potel, in 1903, extended the list to 150 cases; Müller, in 1914, and Geisecke in 1915 made careful studies and the latter author cites 196 cases.

Dr. Hamlin Mattson, of our city, who reported a case in October, 1934, in the *Journal of the American Medical Association*, of such a tumor, states that about 200 of these cases have been reported in the literature, quoting W. P. Graves for this statement.

In studying these cases it might be wise to review briefly the anatomy as well as the anatomical relations of the vagina.

The vagina extends from the vulva upwards and backwards for about three inches. Its anterior wall measures only about 2 inches, whereas the posterior wall measures 3 inches.

There are two layers of muscles, an internal circular one, and an outer longitudinal. There is no true sphincter for the vaginal orifice, but the anterior fibers of the levatorani and the superficial perineal muscles act as a sort of sphincter.

The naked eye appearance of the vaginal wall shows transverse rugæ, and these are seen both on the anterior and the posterior aspects. Microscopically, the mucosa consists of connective tissue papillæ which are covered by several layers of squamous epithelium and has no mucous glands or ducts. The vaginal secretion is a transudation from the blood vessels mixed with mucus which is secreted by the cervix. The presence of the bacillus of Döderlein causes an acid reaction of the vaginal secretion. The vaginal portion of the cervix also consists of squamous cell epithelium.

The anatomical relations of the vagina are as follows: In front the vaginal wall is in relation to the urethra and the neck of the bladder, and hence a sound or catheter passed into the urethra is distinctly felt through the anterior vaginal wall. The neck of the bladder is also palpable through the anterior vaginal fornix, and it is possible that a body, such as calculus or tumor in the bladder, can be recognized on bimanual examination.

Behind, it is separated from the anus by the perineal body, above which we find the recto-vaginal septum. Foreign bodies or feces in the rectum are easily felt through the posterior vaginal fornix and wall.

Vaginal tumors are very rare. The most common tumor of the vagina is the cysts, and next in order is the fibroids. Carcinoma is probably never primary. Sarcomata are, at times, seen in children, and secondary nodules of chorio-epithelioma, and even tuberculosis nodules have been described.

Most authors agree that the etiology of fibroids is unknown. Some authors have explained them on the same basis as uterine fibroids and adenomyomata. Most of these cases occur in the third or fourth decades of life, although they have been occasionally reported in children.

Classification.—Fibroid tumors having their origin in the uterus, which have grown down into the connective tissue and forced their way into the vagina, are excluded from this classification. Also pedunculated growths in the cervix that become adherent to the vaginal wall do not belong in this group.

Location.—True vaginal fibroids develop mostly on the anterior vaginal wall, though cases have been found rarely on the posterior wall.

Form, Size, and Appearance.—Most authors agree that these tumors are usually single, although apparently multiple fibroids have been reported. They appear as hard, round, nodular tumors, usually of small size, although larger tumors have been described, the average size being one or two inches in diameter. One fibroid has been reported that weighed 625 grams. They grow from beneath the mucus membrane of the vagina and are frequently pedunculated, though sessile tumors are more frequently described. They are covered by a fibrous capsule and on the anterior surface the mucus membrane of the vagina covers the tumor mass. Ulceration of the mucus membrane is often seen, due to irritation from friction, etc.

Histologically, the picture is much the same as that found in fibroids of the uterus, and are made up of smooth muscle bundles and connective tissue in variable proportions and more or less fibrous tissue.

Degeneration, which takes place in fibroid tumors of the uterus, has been noted also in the vaginal type of fibromata.

Effect of Pregnancy.—If pregnancy occurs, these growths may enlarge tremendously, much the same as is seen in uterine tumors.

Symptoms.—If the growths are small, there are no symptoms noted and the mass may be found during a routine physical examination. If, however, the tumor is large, the patient will complain of a swelling in the vagina, and may have some discharge, mucoid or even bloody, depending upon the presence of ulceration. Bearing down pains or symptoms due to pressure, especially upon the bladder or rectum, are present in the larger growths. In the presence of a tumor of any size, dyspareunia is common, and sexual relations are not possible.

Diagnosis.—It would appear that the diagnosis should be simple, but at times it may be very difficult, due to its rarity. If the tumor is so large that it distends the vagina it is not possible to ascertain the site of the growth and it may be difficult to differentiate it from a vaginal cyst.

Treatment.—This is surgical and offers no difficulty, as a rule. If the mass is pedunculated, it is very easily removed, after which the vessels are ligated and the vaginal edges are brought closely together.

The prognosis is always good. These tumors do not recur.

Case Report

Mrs. L. E. N., a housewife, forty-six years of age, came for examination relative to a laceration she believed she had received at the birth of her last child eleven years before. She had no complaint except that a mass seemed to descend into the vagina on voiding. She had no urinary symptoms and no pain. There was some inclination to constipation. She had noticed no discharge.

The family history was negative and aside from a gall-bladder attack several years previous her past history was irrelevant.

Examination showed a fairly well-nourished woman of 112 pounds, somewhat pale. Her blood pressure was 164-90, temperature 99.6, pulse 124. There appeared to be a widening of the palpebral fissures. No murmurs were heard in the heart and the lungs were normal.

Menstrual history had been normal, two pregnancies had been carried to full term and there had been no abortions. On pelvic examination there was a tumor about the size of a large orange protruding from the anterior vaginal wall. The urethra was pushed down and seemed outside of the tumor. The mass was completely outside the labia and it was with some effort that it was pushed back into the vagina. There was an old laceration, grade 2, of the perineum. The uterus seemed normal in size and was freely movable. The adnexa were normal. Large vessels were apparent on the anterior wall of the vagina.

Radiograph of the bladder region showed no evidence of calculi. A rounded area of density was seen above the pubic bone, the tumor having been pushed into the vagina for this examination.

Due to our inability of making a diagnosis, consultation was asked, and Dr. Meland examined the patient on May 2, 1940. Cystoscopic examination was made and Dr. Meland gives the following report: "There was a large mass in the anterior wall of the vagina, which presented through the introitus. The size of the mass was that of a small grapefruit. The urethral orifice is eccentrically placed on the left anterior surface of the mass. Catheter could be passed without difficulty. Following this the patient was cystoscoped. The urethra was somewhat tortuous but was not involved by extension from the growth. Bladder was normal. Both ureteral orifices were normal. Diagnosis: Tumor of the vaginal wall which has not invaded the urethra."

Blood examination showed: hemoglobin 84%, red blood count, 4,400,000; white blood count, 9,000. Meinicke negative. The urin was normal on examination.

Operative Procedure: Incision was made longitudinally below the urethra down toward the cervical

area, through the mucous membrane and fascia, after which the mass was removed by scissors and blunt dissection. The bleeding vessels were clamped and ligated. About 2 inches of the mucous membrane of the anterior vaginal wall were removed, after which it was sutured transversely in two layers. A small catgut drain was laid in the upper angle, and the vagina was packed with small iodoform gauze.

The tumor measures 5.5 by 7 cm. and weighed 110 grams.

Pathologic report: Fibromyoma, benign.

The patient remained in the hospital from May 7, 1940, to May 20, 1940. The wound was entirely healed, and she has had no recurrence nor difficulty.

I wish to express my gratitude to Dr. Ernest Meland, Dr. Skjold, and Dr. Baker, for their interest in the preparation of this report.

Discussion

Dr. J. M. Hayes: I have been much interested in the injection method of treating hernias ever since Drs. Bratrud and McKinley started this method at the University about ten years ago. I was there on alternate days with these men and started to do the injections about the same time. While I have not been so enthusiastic about this procedure as they have, I do believe it has a place in the treatment of hernia.

I have used injections for certain classes of cases during these ten years. There is no doubt but what there is a high rate of recurrence.

Injections do work well in children when properly done, but the time required and the need for repeated injections often prove objectionable. For men who have a job and do not desire to lay-off long enough for operation, this method is quite satisfactory. They may come to the office and be injected and go back on the job without losing time. When the hernia seems cured, they are discharged and told to come back any time there seems to be the slightest recurrence. If there seems to be any recurrence, they are given some more injections. Many patients go on this way with no inconvenience except that of repeated injections.

Those who can readily afford the time and expense I advise to be treated surgically.

Dr. Stanley Maxeiner: Hernias in children frequently disappear following the use of trusses only to reappear later in life when they engage in heavy lifting or athletics. It is my opinion that occasionally postoperative hernias are only the recurrence of a childhood hernia which has been brought about by loss of weight, attenuation of muscle and a loss of muscle tone which results in the reopening of a sac which has never been destroyed.

The United States government does not indorse hernia injections and as a result, this treatment has not been used in our experience at the Veterans Hospital.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of December 11, 1940

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 11, 1940. Dinner was served at 7 o'clock and the meeting was called to order at 8 p. m. by the president, Dr. James Johnson.

There were fifty-four members and one visitor present.

The following officers were elected for the year 1941:

President—Dr. John Armstrong, Saint Paul
Vice President—Dr. Martin Nordland, Minneapolis
Secretary-Treasurer—Dr. E. V. Kenefick, Saint Paul

The secretary read a letter from Mrs. C. B. Wright expressing appreciation for the memorial to Dr. Wright which was read at the November meeting of the Academy.

Dr. Martin Nordland read the following memorial to Dr. Herbert Jones.

HERBERT W. JONES
1873-1940

Dr. Herbert W. Jones, a member of the Minnesota Academy of Medicine since 1911, died suddenly on July 9, 1940. He was a native of Wisconsin, born in Berlin, October 13, 1873, and there he received his early education. His medical course was completed at the University of Minnesota in 1902. His early association with Dr. W. A. Jones prompted him to go to Vienna in 1906 to study neurosurgery. Because of his continued interest in this subject, he developed unusual skill in brain surgery. His thesis read before the Academy in February, 1911, was concerned with the problem of brain surgery.

He was married to Margaret Daniels of Minneapolis in 1909. To them were born three sons, Herbert, Jr., Roderick and David. In spite of his large practice, he found time for companionship with his family and devoted much time to the raising of his sons, one of whom, Herbert, Jr., had the good fortune to practice with his father for a short time. Dr. Jones was very fond of boys and through his generosity several young men were assisted in getting a higher education.

Dr. Jones, a member of the M Club, continued his interest in the University after his graduation. He was very active in the Medical Alumni, for which organization he had served as secretary and president. He belonged to the Nu Sigma Nu medical fraternity and was an honorary member of the American Neurological Association. Besides the Minnesota Academy of Medicine, he was a member of the American Medical Association and the state and county societies. Dr. Jones was a member of the Asbury and Northwestern staffs and was president of the latter in 1936 and 1937.

Farming was his hobby and in the latter years he gave much serious attention to the management of the farms which he owned. Death came to him while he was returning from his farm at Cottage Grove, Minnesota.

Dr. Jones was an earnest, serious worker and a true friend. He enjoyed the meetings of the Academy and attended with regularity.

The scientific program followed.

PANCREATIC LITHIASIS

Albert M. Snell, M.D.
Rochester, Minnesota

Abstract

Eighteen cases of pancreatic lithiasis have been encountered at the Mayo Clinic during the last three years. Roentgenologic evidence of stone was present in each instance; in six cases the diagnosis was confirmed by surgical exploration and in two others the diagnosis was substantiated by necropsy. Review of the literature reveals an increasing number of cases of pancreatic lithiasis and there is much to suggest that the condition is not nearly so uncommon as was formerly believed.

The usual effect of pancreatic stone is destruction of the pancreas; the acinar tissue is destroyed first by a process of fibrous atrophy and fatty replacement. The islands of Langerhans usually are preserved until late in the course of the disease. The principal clinical symptoms are pain of a colicky nature; motor disturbances of gastro-intestinal function, steatorrhea and complicating disorders including fulminant infections, such as tuberculosis, endocarditis, and pylephlebitis, are fairly common.

When the pancreas is more or less completely destroyed, fatty metamorphosis of the liver may ensue. It is suggested that roentgenograms of the pancreatic area should be made of patients who present (1) obscure attacks of abdominal pain or gastro-intestinal "storms" of uncertain origin, (2) diarrhea with fatty stools, (3) unexplained enlargement of the liver with or without ascites, (4) diabetes, particularly if it be associated with such abdominal symptoms as colic or diarrhea, or (5) jaundice of indeterminate origin. The roentgenologic picture is itself characteristic and in most instances should suffice to make the diagnosis.

Treatment of pancreatic stones is necessarily a surgical problem. It is of interest to note that neither pancreatitis, peritonitis nor pancreatic fistula appear to be particularly common during the postoperative state. Early diagnosis should lead to successful treatment in a substantial number of cases.

Discussion

Dr. H. B. Zimmermann, Saint Paul: I would like to ask Dr. Snell if any of the patients have been relieved by removal of the stone.

Dr. Snell: This question may be answered in the affirmative. When it has been possible to remove stones from the pancreatic duct, relief has been obtained. A few successful surgical procedures have been reported at the clinic and elsewhere. Most of the patients are seen very late in the course of the disease and are beyond the reach of surgical treatment.

Dr. C. N. Hensel, Saint Paul: Is any special roentgenologic technic used for locating the stones?

Dr. Snell: I think only what would be advised for locating stones of the kidneys and ureters. It is unfortunate that I did not bring some of the original films of these stones to demonstrate. The shadows are opaque and often can be seen throughout the course of the pancreatic duct. There is diagonal distribution of shadows at about the level of the first lumbar vertebra which can be seen easily on either side of the vertebral column. They are usually demonstrated in oblique views of this region.

SOLITARY(?) MYELOMA OF THE SPINE WITH CORD INVOLVEMENT

Case Report

Gordon R. Kamman, M.D.
Saint Paul

Mrs. M. N. a widow, aged sixty-nine, was seen in consultation at St. Joseph's Hospital with Dr. W. H. Von der Weyer on October 9, 1940.

The family and past medical histories were irrelevant to the present complaint. Mrs. M. N. stated that aside from "a little arthritis of the spine" in the fall of 1939 she was well until May 18, 1940. On that date while entering a street car she fell landing on the left hip. The conductor helped her up and she boarded the car. There were no immediate symptoms other than generalized aches and pains. Two days following the fall she consulted her family physician who found that the left 9th rib had been fractured. There also was a hematoma of the left hip. The left chest was fixed with tape which the patient wore for about two weeks. During that time her progress was satisfactory and there was no trouble in her legs. About one week after the accident she began to have pain in the *right side* at about the same level at which the rib had been injured on the left. At first this pain was localized but in about two weeks it had assumed girdle characteristics involving the left side as well as the right. The pain was severely aggravated by coughing, sneezing or straining. The patient stated "I have prayed constantly that I never would have to cough." About three months after the accident Mrs. N's legs began to feel numb. This was about August 10, 1940. The numbness started between the knees and the ankles and in one or two weeks had extended above the knees and up to the level of the girdle pains previously described. Shortly after the numbness began the legs grew weak and this weakness increased. For nine days prior to my first examination on October 9, 1940, the patient had been unable to walk. There was no disturbance in sphincter functions and no symptoms referable to the upper extremities or cranial nerves.

The neurological findings were confined to the lower extremities. There was a flaccid paraplegia with preservation of the knee and ankle jerks. There was an extensor plantar response on the left and a positive Chaddock on the right. There was bilateral abortive clonus. The sensory examination revealed the absence of pain sense from the 9th dorsal dermatome down. Temperature sense was intact. Touch sense was absent on the right from the knee down and the lower half of the left leg. Vibration and passive motion were impaired in both ankles.

The diagnosis at that time was incomplete trans-

verse lesion of the spinal cord at the 9th dorsal segment (opposite seventh dorsal vertebra).

Radiographs made of the spine were negative except for marked hypertrophic arthritis involving the dorsal spine and old compression fractures of the bodies of the 12th dorsal and 1st lumbar vertebræ. There also was rather a sharp localized scoliosis of the upper dorsal spine toward the left side. There was no evidence of destruction of the pedicles or the laminæ of any part of the spine.

On October 11, a spinal tap was performed with the patient in the lateral recumbent position. The fluid was clear, slightly yellow and under 8 mm. mercury pressure. On strong juglar compression the pressure rose slowly to about 9 mm. and did not fall upon release of the juglar compression. Upon examination of the fluid one lymphocyte was found. The Wassermann reaction and colloidal gold curve were negative but the protein was elevated to 144 mm. per 100 c.c.

On October 16, 1940, the neurological examination showed the absense of both touch and pain sensation from the 7th dorsal dermatome down and there was paralysis of bladder and bowel functions. My notes made at that time read "This constant sensory level together with the subarachnoid block as demonstrated on the Queckenstedt test together with the elevated CSF protein leads to a diagnosis of rapidly increasing compression of the spinal cord at the seventh dorsal segment. Advise immediate exploration through laminectomy of the third, fourth and fifth dorsal vertebræ." The operation was performed on October 19 by Doctor Von der Weyer. As the neural arch of the fourth dorsal vertebra was exposed some granulation tissue came into view. The arches of the 3rd and 5th dorsal vertebræ were taken off and a mass about two inches in length was encountered. This mass was a dark mahogany color, had a smooth glistening surface and was irregularly shaped. It was entirely extradural. The mass was removed, bleeding controlled and the wound closed in the usual manner. Mrs. N. failed to rally from the operation and died six hours afterwards. Permission was requested for an autopsy but refused.

The pathologist's report submitted by Dr. Thomas J. Kenyon, pathologist at St. Joseph's Hospital, was as follows:

"*Gross.*—On sectioning the tumor it appeared to be composed of white rather friable material.

"*Microscopic.*—The tumor was composed of numerous distinct cells which appeared rather closely packed together. The outline of the cell can be sharply demarcated from the adjoining cell. The nuclei are pushed eccentrically and suggest a plasma type of cell. This picture is frequently seen in multiple myeloma. While there does not appear to be any obvious involvement of the bone with this specimen it is possible this tumor could have extended from the portion of the vertebræ lying more ventrally.

"*Diagnosis.*—Multiple myeloma.

"Later pieces of the bony laminæ removed at the operation were decalcified and numerous plasma cells are noted which are typical of multiple myeloma."

In this case we have no proof whatever that we were dealing with a solitary myeloma. The patient died before we knew the pathological nature of the lesion so radiographs of the skull and long bones were not made. However, it can be said that radiographs of the vertebral bodies as well as ribs and clavicles did not show any myelomatous involvement.

About twenty cases of solitary myeloma are reported in the literature. Some of these showed involvement of the femur, others of the clavicle, one of the mandible, and several of the vertebræ.

Solitary myelomas may be divided into two groups—

1. Those which started as a single lesion and subsequently became generalized.

2. Those in which the lesion remains solitary during the entire period of observation either until the death of the patient or at the time of the original report.

The question arises as to whether or not all solitary myelomata would eventually become multiple. I believe the answer is found in the fact that cases have been reported of solitary myelomata of four, nine and ten years' duration. The question occurs to me as to whether solitary myelomata of this nature and the classical multiple myelomata which are seen so much more frequently are the same pathological entity.

In our case no opportunity was had to determine the Bence-Jones protein in the urine. In the cases reported in literature this was found in practically all of the multiple myelomata and in a fairly high percentage of the solitary ones.

The only similar case found in the English and German literature was one reported from the Massachusetts General Hospital in the early part of this year. It was the case of a patient suffering from a paraplegia of fairly rapid onset. X-ray studies of the spine were negative but at the time of operation involvement of the 11th dorsal lamina was seen. This patient was still alive at the time of the report.

Discussion

Dr. A. W. Adson, Rochester: The case with myeloma reported by Dr. Kamman is unique as far as my limited experience is concerned, since it occurred late in life, grew unusually rapidly and was but a single lesion. I recall two patients on whom I performed laminectomy to relieve cord compression. One was a male who presented a high dorsal lesion with bony destruction of the pedicle. The neurologic symptoms were those of radiculitis and beginning cord compression. Numerous roentgenograms of the spine, skull, long bones and pelvis failed to reveal other lesions. The laminectomy uncovered a friable, reddish, pulpy mass which proved to be a myeloma on pathologic examination. The patient was advised to have massive doses of x-ray therapy. This advice he accepted and went to the Memorial Hospital of New York for his treatment where he received tremendous doses of high voltage therapy. In spite of this, he succumbed to his disease in about two years. Although he had but one obvious lesion at the time of his laminectomy, others soon made their appearance. Therefore, the most that can be hoped for from a laminectomy and partial removal of an intraspinal myeloma is very slight temporary relief. About the same amount of relief is to be expected as from a laminectomy and partial removal of a metastatic lesion of the spine, a result which scarcely justifies the surgical hazard.

The second patient presented the usual symptoms of an intraspinal tumor. Roentgen rays of the local area of the spine failed to reveal bony destruction. After the pathologic diagnosis was made on the tumor tissue, additional examination of the bones revealed other lesions. Again the outcome was the same, a gradual decline with a cachectic death.

Dr. John F. Noble, Saint Paul: I have had no personal experience with the so-called solitary myelomas. Many of these tumors thought to be solitary will, if followed over a long period of time, prove eventually to be multiple. The generalized character and the destructive nature of the disease was emphasized to me by a case observed at autopsy by one of the men in the department of pathology at the University of

Minnesota. In his zeal to do a complete study of a case of multiple myelomata at autopsy, he took specimens of bone from the spine. The gross appearance of the bone was normal and x-rays of the spine just before death had showed no evidence of tumor involvement. After decalcification, the specimens of bone from the spine in microscopic section showed typical myelomatous infiltration. If, then, bone which is normal in appearance on x-ray and gross examination, can be proved to contain myelomatous tumor cells, I believe we should accept solitary myelomas only after very careful clinical study and autopsy examination.

Dr. Kamman (in closing): I felt, like Dr. Adson, that multiple myeloma was more likely to be found in young people; but, in looking over Peet's case reports, I noticed there were several patients in the middle age group. Doctor Noble's remarks concerning myelomatous involvements being discovered only after decalcification of the vertebral bodies were very interesting. It goes to show that one can have serious and fatal involvement of bones without roentgenographic evidence early in the course of the disease. In my patient we did not have time for x-ray studies of the skull and long bones because she died six hours after operation.

I still feel, of the cases of solitary myeloma seen, many will become multiple if the patients live long enough. However, there must be such a thing as solitary myeloma. Whether the pathologic changes are the same, I cannot say; but there seems to be abundant clinical evidence to show a solitary myeloma can go on indefinitely without becoming multiple.

The meeting adjourned.

E. V. Kenefick, M.D., *Secretary.*

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

Manual of Clinical Chemistry. Miriam Reiner, M.Sc., Assistant Chemist to Mount Sinai Hospital, New York. Introduction by Harry Sobotka, Ph.D., Chemist to Mount Sinai Hospital, New York. 296 pages. Illus. Price, $3.00, flexible binding. New York: Interscience Publishers, Inc., 1941.

Manual of Physical Diagnosis With Special Consideration of the Heart and Lungs. Maurice Lewison, M.D., Professor of Physical Diagnosis, University of Illinois College of Medicine; Consulting Physician, Cook County Hospital; Attending Physician, Mount Sinai Hospital, Chicago; Formerly Attending Physician and Chief of Tuberculosis Staff, Cook County Hospital; and Ellis B. Freilich, M.D., Associate Professor of Medicine, Cook County Graduate School of Medicine; Attending Physician and Chief of Tuberculosis Staff, Cook County Hospital; Consultant to the Chicago Municipal Tuberculosis Sanitarium; Attending Physician, University Hospital; Associate Attending Physician, Mount Sinai Hospital, Chicago; In Collaboration with George C. Coe, M.D., Instructor of Medicine, University of Illinois College of Medicine; Associate Physician Cook Co. Hospital; Chinical Assistant, Mount Sinai Hospital, Chicago. 317 pages. Illus. Price, $3.00 cloth. Chicago: Year Book Publishers, Inc., 1941.

Born That Way. Earl R. Carlson, M.D. 174 pages. Price, $1.75, cloth. New York: John Day Co., 1941.

Physiology in Modern Medicine—Macleod's. Ninth Edition. Edited by Philip Bard, Professor of Physiology, Johns Hopkins University School of Medicine, with collaborators. 1256 pages. Illus. Price, $10,000, cloth. St. Louis: C. V. Mosby Co., 1941.

An Introduction to Dermatology. Fourth Edition. Richard L. Sutton, M.D., Sc.D., LL.D., F.R.S. (Edin). Emeritus Professor of Dermatology, University of Kansas School of Medicine; and Richard L. Sutton, Jr., A.M., M.D., L.R.C.P. (Edin). Assistant Professor of Dermatology, University of Kansas School of Medicine. 904 pages. Illus. Price, $9.00, cloth. St. Louis: C. V. Mosby Co., 1941.

Electrocardiography in Practice. Ashton Graybiel, M.D. Instructor in Medicine, Courses for Graduates, Harvard Medical School; Research Associate, Fatigue Laboratory, Harvard University; Assistant in Medicine, Massachusetts General Hospital; and Paul D. White, M.D. Lecturer in Medicine, Harvard Medical School; Physician, Massachusetts General Hospital in charge of the Cardiac Clinics and Laboratory. 319 pages. Illus. Price, $6.00, cloth. Philadelphia: W. B. Saunders Co., 1941.

THE POISON TRAIL. William F. Boos, M.D. Cloth, 380 pages. Price $3.00. Boston and New York: Hale, Cushman and Flint, 1939.

The author, now seventy, has had an interesting career in medicine and toxicology. He received his A.B. at Harvard in 1894, Ph.D. in Chemistry, Heidelberg, in 1896 and M.D., Harvard, in 1901. Early becoming interested in medicolegal investigations he has served as medical expert and toxicologist for the government since 1908 and has held other important positions in the same connection. He has made many contributions to scientific literature on chemical subjects and subjects relating to internal medicine, occupational poisoning and public health.

This is the author's first book, well and interestingly written for lay consumption. It is practically an autobiography, covering his own experiences with various poison cases and giving much information of value regarding the different poison agents involved. Written almost like a novel it is easily read and highly informative. It especially emphasizes the necessity of keen, systematic and competent investigation in all medico-legal autopsies where poisoning is a possibility.

Equally illuminating are the author's comments on canned foods. In the last fifteen years he states that he has investigated countless charges against the food canning companies, yet in all that time he failed to encounter a single authentic case of food poisoning of any kind traced to commercially canned food and he has yet to hear of one, although the contents of millions of cans are consumed daily throughout the United States.

A book like this should go far to dissipate the ignorance and superstition which has lingered so long in the public mind over the various matters with which it deals.

Gilbert Cottam.

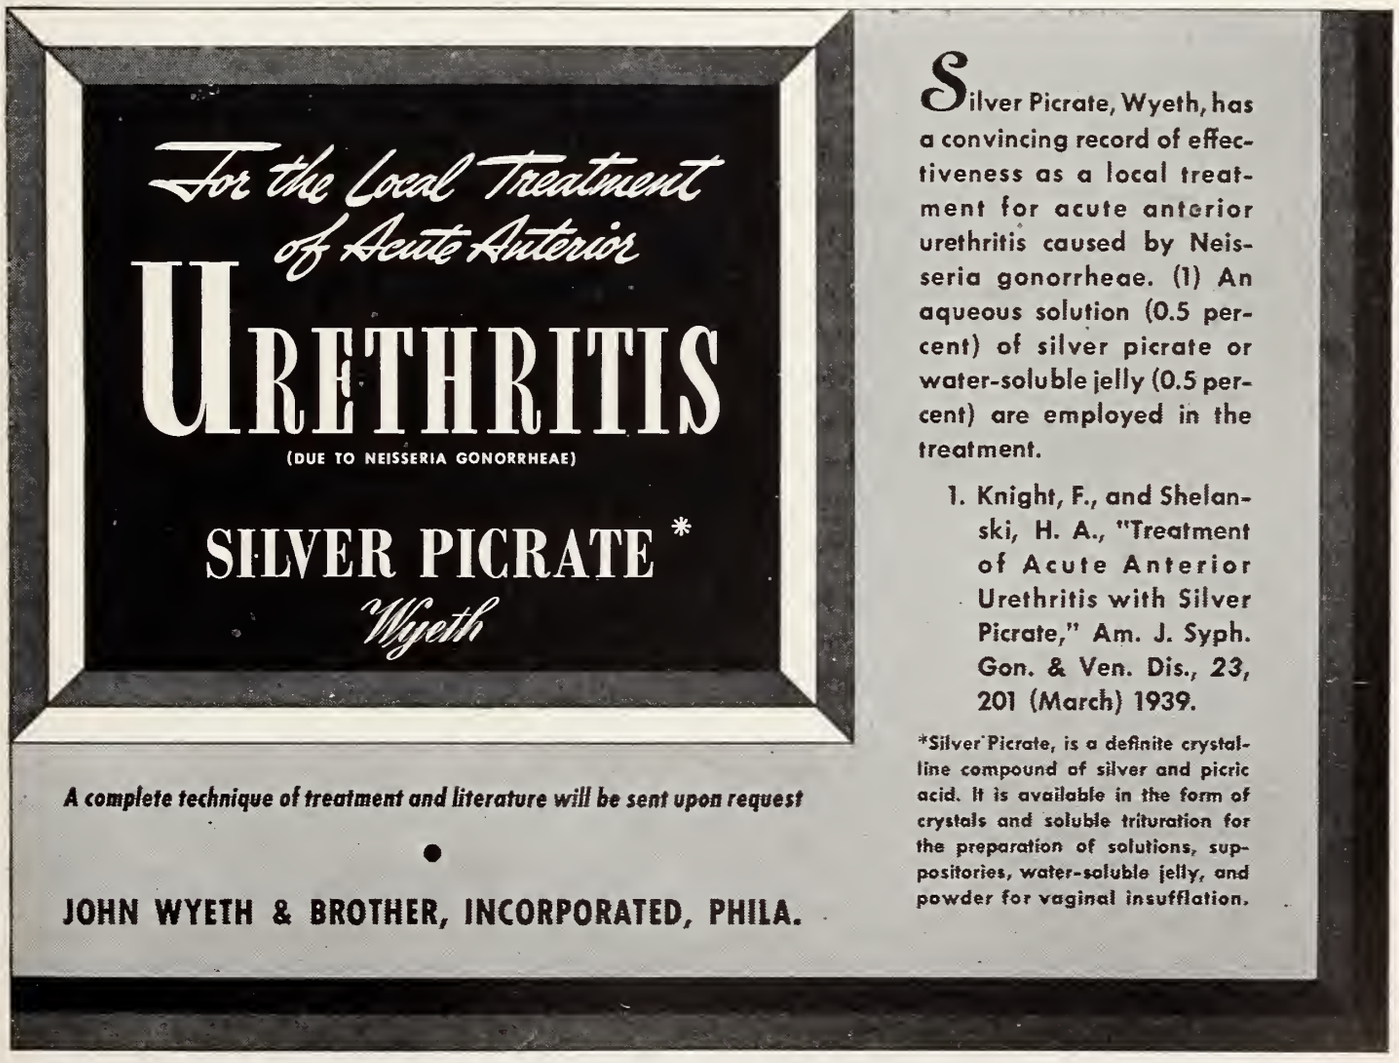
GRADUATE MEDICAL EDUCATION. Report of the Commission on Graduate Medical Education. 304 pages. Chicago: University of Chicago Press, 1940.

The Commission on Graduate Medical Education was organized for the purpose of formulating the educational problems and principles involved in the medical training of graduates and the adequate development of specialists, whereby they might be kept abreast of new developments in diagnosis, treatment and prevention.

A detailed consideration is given to the training of interns. Suggestions are offered in regard to a desirable length of service, the requirements of a satisfactory service and the various responsibilities of the intern, the hospital authorities and the medical staff of the institution. The general purpose should be a preparation for general practice with this goal in the minds of all those who may participate in the various features of this process. When feasible, or possible, opportunity should be offered for a progression into special fields.

In certain hospitals with adequate teaching facilities and with the opportunities for wider experience, residencies may be established whereby selected students and interns are rendered broader fields for personal development along special lines of work, at the same time utilizing the talents of the applicant for the promotion of better teaching among the interns.

Graduate education among the men in practice is stressed and the plans in various states discussed, pointing out similar and varying features which have proved advantageous. This method of teaching is intended to aid not only those on general practice particularly, but also specialists. It must always be the primary goal to make any course offered attractive in form and variety, topical in its appeal, but also convenient, concise and cognizant of economic expediencies.



Specialty boards must look to proper allocation of specialists so as to avoid an over-supply in certain areas, as already appears the trend in middle-sized cities. Certification will no doubt become more difficult, but it must be realized that the certification of men already doing special work has been necessarily facilitated, lest retroactive measures prove unjust to the applicant. The boards have already done excellent work and no doubt will continue to do so in withholding recognition from those who are inadequately fitted by training or personality.

Some consideration is given to a discussion of graduate teaching in England and parallels drawn with methods in this country.

The method of graduate instruction as pioneered by the University is quite fully discussed and its attractive features stressed.

For anyone interested in graduate medical education the book supplies much valuable and instructive material, compiled by a commission which has the weight of authority, good judgment and experience.

FRANK J. HIRSCHBOECK, M.D.

CANCER IN CHILDHOOD; AND A DISCUSSION OF CERTAIN BENIGN TUMORS. Edited by Harold W. Dargeon, M.D., F.A.A.P., Attending Pediatrician, Memorial Hospital for Cancer and Allied Diseases, New York. 114 pages. 42 Illus. 9 Tables. Price, $2.70. St. Louis: The C. V. Mosby Company, 1940.

The reader of this symposium will ever be alert to become constantly aware of the prevalence of cancer and allied diseases in the infant and the child. The author has well emphasized childhood cancer as one of the important children's diseases.

The author has acknowledged the generous grant received from the estate of the late Elizabeth Edwards, making possible the free distribution of this book to a number of libraries. It is the recommendation of the reviewer that this volume be added to the educational list in the Cancer Movement.

LILLIAN L. NYE, M.D.

CLINICAL DIABETES MELLITUS AND HYPERINSULINISM. Russell M. Wilder, M.D. 459 pages. Illus. Price $6.00. Philadelphia: W. B. Saunders Company, 1940.

The book, Clinical Diabetes Mellitus and Hyperinsulinism by Dr. Russell M. Wilder, is indeed a fine addition to this subject. This book is written in a very readable and understandable style. It should be very welcome to the rank and file of physicians who are called upon to treat diabetes but do not necessarily limit their practice to it.

The development of each chapter in the book is logical. The author begins with a clear delineation of the primary factors that come to play in the maintenance of the normal blood sugar level. In the preface the author states "Purposely omitted from this book is extensive consideration of the theory of carbohydrate metabolism, the physiology of experimental diabetes, and the pathology of diabetes." This premise makes this volume fully a clinician's monograph.

In the exhaustive second chapter diabetes mellitus is defined and the methods for its diagnosis established. The reader has carefully called to his attention certain of the otherwise confusing non-diabetic melliturias. A lucid description and differentiation is made with regard to renal glycosuria (the so-called normoglycemic dextrosuria), alimentary hyperglycemia and diabetes innocens all of which terms have at times provoked much confusion.

Dietary management of the diabetic, diabetic cookery, insulin therapy and the requirements for effective therapy, all receive exhaustive consideration.

In Chapters 10 and 11 the author discusses acidosis and coma in diabetes, as well as infections complicating diabetes. Both of these chapters are highly recommended to the reader because of their orthodox and well tried therapeutic programs that they preach. One would do well to refer over and over to their well chosen words of admonition and advice. Full consideration is given in succeeding chapters to complications of every manner that the diabetic like any non-diabetic may fall heir to.

The last several chapters in the monograph are given over to that interesting subject of hyperinsulinsim. The author is in a unique position to write authoritatively on this important subject because of his extensive and pioneering experience. Adequate discussion is given to the methods necessary to make this diagnosis. Medical and surgical management is presented.

The author on page 19 states, "Those who adhere to the unitarian conception of diabetes, as I do, define this disease as an abnormality of metabolism created by insufficiency of the insular activity of the pancreas. In diabetes the homeostasis of the blood sugar level is permanently disturbed." Dr. Wilder gives a great deal of force and vigor to his unitarian stand. The entire volume reads well and logically. The author has made full use of many footnotes which may prove a bit disturbing to the continuity by some readers because of their newness in medical writings, but certainly serve a most useful purpose. They are much like "stage whispers," fortifying and accentuating the main thought. Many bits of interesting information were placed in these foot notes. Their use was indeed most refreshing. In the foot note on page 68 the author makes an almost prayer-like point when he says, "Another dramatic illustration of the far-reaching influence of the discovery of insulin is provided by the rescuing from premature certain diabetic death of the Nobel Prize Winner, Dr. George Minot. Dr. Minot later was able to contribute importantly to the discovery of the effective treatment of pernicious anemia, and thereby prolonged other valuable lives to add to the sum of values of communal life."

This volume by Dr. Wilder is a highly clinical and exhaustive treatment of the subject of diabetes and hyperinsulinism which will be found extremely acceptable.

SIMON G. SAX, M.D.

AS I REMEMBER HIM. Hans Zinnser. Price $3.50. Boston: Little, Brown and Company, 1940.

We venture to predict that this delightful volume will be recorded among the best of the year.

Purporting to be the life and thoughts of another, it is in fact the autobiography of a physician. The many entertaining anecdotes make it easy reading, but there is interspersed throughout the book evidence of deep thought.

After reading the book one wishes he could have known the author.

C. B. D.

DON'T EAT BREAD. Allen Klein, Ph.G. 116 pages. Price, cloth, $1.00. Emmaus, Pa.: Rodale Press, 1939.

The Greeks had a word for it, "diatribe," a wearing away of time. Intended primarily for reading by the layman, this little volume by specific statement as well as implication charges the cereal grains wheat, rye and corn with direct or contributory causation of an astonishing number of the human ailments and infirmities to be found listed in any standard medical dictionary between the extremes of ā a ā disease and Z.Z.'Z." The author modestly states: "This book offers irrefutable proof, based on medical authority, that *wheat and some of the other grain cereals* are the causes of undernutrition, obesity, and a host of present-day ills." The major premise remains unsupported even after reading the text.

GOUT—A FORGOTTEN DISEASE*

E. L. TUOHY, B.A., M.D., F.A.C.P.
Duluth, Minnesota

MANY years ago a querulous man hobbled into my examining room berating fate, doctors and pharmaceuticals because his "rheumatism" was killing him and no relief was forthcoming. He was obese and conditionally alcoholic. That, defined, means his truculence was only enhanced by periods of sobriety. His lament as to medicine arose from the circumstance that five years previously a doctor in Georgia had given him some medicine that "cured" him overnight. All medicine taken since that time suffered equally with him in exhibiting superb futility.

To look at him casually, one would say "rheumatoid or infectious arthritis." Yet, while he later suffered some permanent osteo-arthritic changes, the joints most painful and swollen retained no essential disability in remissions. Casting about for an answer to the identity of this wholesome and overnight Georgian remedy, it suddenly dawned upon me "this man must have gout." And so began a long association with a man who taught me a great deal about gout. On many occassions, I confess, he must have passed fully out of my mind, for I know I join with most Minnesota physicians in frequently overlooking gout. Indeed, "out of mind is out of heart."

It is for this reason that I title my discussion "The Forgotten Disease." Somehow there has grown up a tradition that gout is a disease of Merrie Old England, and that it occurs but rarely in America. There are no present available statistics for gout with us. It is very poorly cross-indexed in our clinics and hospitals; it likely never figures as a primary cause of death; I have never seen it mentioned in our autopsy protocols, even where gout was diagnosed and known to be present in life. For instance, my gouty friend never got over his gout, but it didn't cause his death—that came with hypertensive, myocardial failure. In the course of his stormy life it became harder and harder to terminate his immediate attacks. Once W. A. O'Brien was a visitor. This man came in with a grotesquely enlarged and swollen forearm to the elbow. The hand was puffy, purple red and only moderately painful. To "O.B.," I said, "Take one look and make a diagnosis." He did so and replied, "Lymphangitis." Then I asked him why the man had no fever, and why this came on over night—all too rapidly for any obvious infection. In short, he was quite abashed by my statement that this grotesque arm was gout. I had seen it before. Under colchicum and cinchophen, the arm was normal appearing in thirty-six hours. I have never seen such an extremity in anyone else.

Specialism has carried medical service to the point that, where available, patients are prone to bring their somatic distresses directly to some doctor covering that anatomical assignment. It is good that well trained specialists do not forget constitution and general physical background. An obese butcher, aged 58, is a case in point. He had been a heavy beer drinker and a lover of plenty of fat meat. He selected the fattest cuts and ate the fattest portions. Late in October, 1939, he had complained of ankle soreness and a swelling at the base of the right great toe. A physician advised him to take cinchophen. On November 21, 1939, he consulted Ophthalmologist Frank Knapp on account of a very striking condition suddenly obtaining the previous evening in his

*From the Department of Medicine, The Duluth Clinic. Read before the Minnesota Society of Internal Medicine, Rochester, Minnesota, November 11, 1940.

right eye. There developed an edema, swelling, redness and sense of heat in the right eye. There was no definite pain but a constant sense of itching. Doctor Knapp recognized the oddity of this development and sent him for a general checkup. He volunteered at once the history of beer drinking and fondness for fat, and directed my attention to the pains and distresses in his feet, all betokening gout. We found the uric acid of his blood to be 5 mgm. per cent. This was repeated several times over a period of two weeks and never dropped to our normal* during the period of observation. Suffice it to state that through giving the patient colchicum, modifying his diet and eliminating beer, his eyes were restored to normal in three days.

Thereupon Dr. Frank Knapp went back into the literature and informed me that he did not find much currently, but he found the following which I have excerpted from a report made fifty-six years ago by the famous Jonathan Hutchinson.[5] This is most illuminating.

"There is a condition which, for want of a better name, I have for long been in the habit of recognizing as Hot Eye. It is one of the many curious phenomena which attend quiet gout. I use the term quiet gout as distinct from acutely paroxysmal gout. In families liable to gout, one person who becomes the subject of acute attacks of podagra—what is known as "unequivocal gout"—there are often half a dozen who are the subjects of minor symptoms which denote a similar tendency. . . . Amongst the frequent occurrences which denote its presence are repeated short attacks of congestion of the eye. Usually one only is affected, but sometimes both. The conjunctiva becomes red, and the eyeball feels hot, and pricks, as if sand were in it. The attack may come on within half an hour of the meal which has disagreed, and it may last a few hours, or a day or two.

"A further practical note I must ask leave to make. It is to the effect that many cases of irritable, hyperesthetic and easily tired eyes in young persons are in association with inherited gout. I feel sure that in some of these cases we are in the present day in danger of pushing the recommendation of spectacles to an excess.

". . . Such patients will often state that they are very susceptible to the influence of beer and wine, and that malt liquor and some wines almost always cause indigestion, and make the urine muddy. These dietetic disturbances, to which as a test of gout attention was, I think, first claimed by Sir James Paget, are very important and valuable."

*The uric acid tests have been done in our laboratory with whole blood according to Benedict's modification of the Folin technic with an average normal 3 mgm. per cent. Those using blood serum with blood collected under oil report an average normal of 6 mgm. per cent.

Wood,[9] a South African, as late as 1936 referred back to Hutchinson's article and reported a series where ocular manifestations of gout again appeared exemplifying the outstanding feature of "hot eye." Wood found some association of iritis and some of his cases had gone on to destruction of the eye. Those interested should consult his article.

A certain Slovanian servant girl came under my observation at about the time (1939) that Lockie[6] published his article pointing out the relationship of gout to metabolism of fat. This girl weighed 210 pounds when only seventeen years of age. She oozed through any confining wardrobe. To make matters worse, her considerable surface area gave greater opportunities for expansion to a psoriasis that sort of negatived any incentive to dieting and attaining a svelte silhouette. Nevertheless, there came a day when the family said, "Something must be done about it." She began a period of 800 calorie intake and within eight days had severe gouty arthritis. Immediately, as the ordinary food intake is restricted, an obese subject is automatically exposed to a high fat, or even a ketogenic diet. This may also help to explain exacerbations of gout after operations or injuries where the patient eats much less than usual. I have seen a similar "hot eye" in a very obese young man soon after he went on a restricted diet. I could not, however, establish any hyperuricemia.

According to Hench,[2] not more than 3 per cent of gout occurs in women. This figure seems low. Hill[3] gives his "English statistics" reporting approximately twenty-four per cent in women. Hench and Vanzant collected their cases chiefly in the arthritic section of the Mayo Clinic. The English have had a long historical and literary, not to say political, contact with gout. It is possible that they may attribute over much to gout; and we in America are over-zealous in attempting to attribute much arthritis to focal infection. Confusion is most likely to occur in differentiating rheumatoid arthritis (infectious?) from gout. Indeed, it is possible that both conditions may override.

A woman librarian, forty years old, illustrates the possible diagnostic difficulties. She has the meticulous and exact personality seen traditionally in those women sensing the gradual invasion of an arthritis too obvious to ignore and too silent to disable. She noticed trouble in one

finger six or seven years previously. This joint spindling remained remarkably localized. Before I first saw her she had been given intravenously Wetherby-Clawson vaccine. She was very desi-

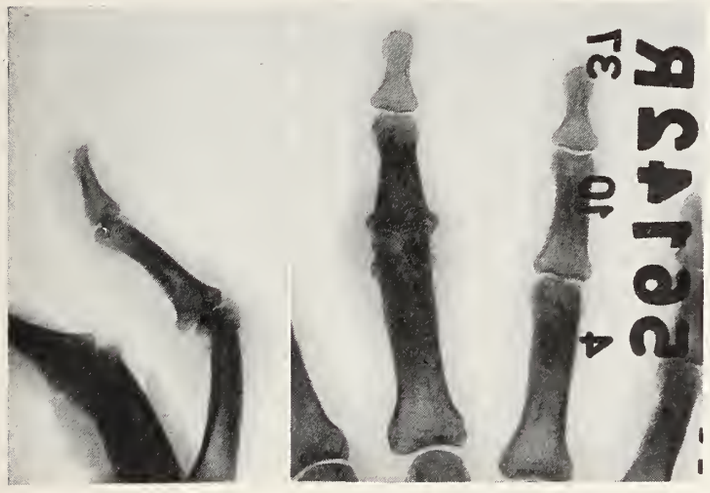

Fig. 1. The woman, aged forty, a librarian, discussed in the text. The punched-out areas are obvious.

rous of continuing it. She never showed any definite reaction one way or another. It was the same with various other methods of treatment tried over a period of three years. She would show an occasional flare-up in this one finger, or a few other finger joints would swell casually. Not until her ankles joined in the progression did I resolve to try out the injections of gold salt. This treatment was carried out meticulously at an arthritic clinic connected with one of our large universities where she spent the past summer doing graduate work. Nothing special happened. She returned to Duluth in the early fall. As long as she rested, she was better; when tired, or using her joint unduly, she was worse.

Suddenly she had a flare-up with especial swelling of the ankles. Then she drew my attention to the very obvious bilateral olecranon bursitis.* Despite normal blood levels (3 mgm. per cent) of uric acid, she has up to date responded to colchicine therapy vastly better than to any previous treatment. It is my understanding that present roentgen opinion does not hold that typical "punched-out areas" are necessarily due to gout. It is also mentioned in various articles in connection with rheumatoid arthritis. Comroe's[1] book gives an outline of roentgen differentiation of gout and rheumatoid arthritis. The reproductions he gives lend confusion, but

*Said to occur three times as often in gout as in any other condition.

that is apt to follow when attempting to reproduce finer roentgen film detail. Figure 1 is a reproduction from this patient. Figure 2 is introduced for comparison from a supposedly "prov-

Fig. 2. This is presented for comparison with Figure 1. The two seem very similar. She consulted me in July, 1940, simply for a check on the uric acid of the blood, while vacationing here. Her story was similar to my patient's—"had been studied at various clinics and universities in Chicago," where, she stated, "they finally decided I had gout although women aren't supposed to have it, and the treatment helped me at once." I found uric acid values to be 3.2 mgm. per cent.

en" instance of gout in a woman, aged fifty-eight.

As to the question of uric acid levels, Hench has reported that he has seen unquestionable gout with uric acid levels as low as 2 mgm. per cent. Smyth[7] reports that he has seen hyperuricemia in members of the families of gouty patients without any special symptoms. I have not seen marked drops in uric acid levels at all proportional to the clinical benefits after treatment with colchicine. In general, therefore, the definite relationship of gout to uric acid still offers many moot problems. While glycosuria occurs in diabetes, no one is likely to confuse either glycosuria or hyperglycemia with the cause of the disease.

As to whether gout is a metabolic disease or not, Talbott and Coombs[8] have studied the problem and their conclusions are noteworthy. Their article should be consulted not alone for this feature, but also for an excellent statement of the

method, the advantages and the rationale of the treatment of gout wih crystalline colchicine, both during acute exacerbations and in quiet remissions.

It remains, therefore, either to affirm or challenge the therapeutic response of 0.5 to 1 mgm. of colchicine given at two or three hour intervals up to tolerance (digestive irritation and diarrhea) as a diagnostic procedure. Colchicum is said to be specific for gout only. Loskie's high fat, low protein and low carbohydrate diet is based on his experience where nine out of ten individuals in remission were given an attack by this diet; and they were promptly taken out of the attack by the administration of colchicine. Therefore, it would appear that high protein diets, as formerly so much held, are less responsible than the "high rich foods" so often consumed with liberal amounts of alcohol by gourmets. The final conclusion regarding diet by Talbott and Coombs agrees with this contention.

Tophi in my experience have been rare, especially in mild or borderline cases. In any case, the literature mentions only a 60 per cent incidence. I recall a man who drew my attention to aural tophi. At the time had no gouty symptoms; however, within a few weeks he developed, after a trivial blow on the lower leg, a very tender, swollen area. It cleared at once with colchicine. I am sure that had I not noticed his ears, gout would never have entered my mind. Later on he developed occasional twinges, but for the most part has very little trouble.

At intervals a chart comes to me and going back over it I notice that I treated obvious gouty attacks in patients who now appear with the infirmities of age. Certain afflictions once established, such, for example, as diabetes, tend to dominate a patient's life. This does not appear to be the situation with most of the gout I have encountered. Hench's well-known "twenty points" (1938) have repeatedly helped to "tune me in on the right wave length" in order to suspect and interpret gout. His citations of sudden development, association with slight trauma, exposure to cold, postoperative reactions, and nocturnal alarms after seasonal, familial or goodfellowship gatherings—all these items so well catalogued by Hench should be occasionally reviewed, both to further our own survival and advance our medical effectiveness.

A 50-year-old, obese executive illustrates this association. Among those who have golfed with him, his proficiency at the nineteenth hole has been the subject of comment and perhaps some emulation. The next day after such an exhibition I saw him with what he called "blood poison" on the dorsum of the foot, occasioned by "the overtight lacing of his shoe." The uric acid of his blood was 5.2 mgm. per cent.

I have made it a point to swear such mild victims of gout to a certain amount of secrecy concerning their disability. In the first place, I have told them that the indications were only suggestive and that it might take two or three decades to establish whether their malady was an accomplishment in good living, or retribution for misapplied efforts. So far as I have been able to judge, there are none so poor that they may not have a gouty inheritance, a love of fatty rich food and a yearning for the cup that cheers. In any case, rich or poor, no gouty subjects get as much sympathy as ribbing—therefore, within reason, they should not broadcast their affliction.

Summary and Conclusions

This conversational account of gout is the disease—chiefly in the atypical form—as I have seen it. It is intentionally drafted to avoid monographic pretentions. I am assuming that where we suspect gout, a voluminous literature from which to refresh ourselves with details is at hand. Gout is practically as enigmatic as when Sydenham had it and described it (see historical review of Hormell[9]). While we may quibble over whether to catalogue it as a metabolic process or not, we cannot deny its familial tendency and constitutional background. Uric acid is deposited in the tissues in certain areas; nevertheless, rich, fatty diets (Lockie) and alcohol (beer and ale) precipitate attacks. These come in individuals with a certain background or gouty diathesis. However, Hench codified a list of many other trigger factors. The disease does not kill and is therefore lost, for the most part, to statistical enumerations. The x-ray offers little in the way of positive selective criteria. Colchicine as a therapeutic test in acute attacks is more determinative than either hyperuricemia, the presence of aural tophi, or bursitic accumulations. Gout is a disease ideally suited to sharpen the physician's clinical acumen and judgment. Without these faculties it will be frequently overlooked.

PRACTICAL POINTS IN FEMALE SEX HORMONE THERAPY*

JAMES R. MANLEY, M.D.

Duluth, Minnesota

THE subject of endocrinology, particularly as related to the female sex organs, presents a fascinating field for study and speculation. The vast experimental work, which is constantly being carried out on laboratory animals, is rapidly correlating the somewhat confusing, isolated findings into a semblance of order, so that we soon will have a perfectly plain rationale of treatment for the hormonal deficiencies.

In my opinion, the greatest weakness in this field of medicine is in diagnosis. This will not be corrected until there are simple, easy laboratory procedures developed, which will allow the practitioner to assay the amounts of the various hormones and their relation to the normal, which may be present in the individual patient. It is true that these tests can be carried out in experimental laboratories now, but they are not yet generally available to the profession. When this condition is corrected, treatment by the practitioner will be conducted on a more rational basis.

The whole subject of female endocrinology is a little confusing at times, particularly in view of the apparent contradictory advice given to use different hormones for the same condition. As an example, both gonadotropic hormone and progesterone are advised in the treatment of functional uterine bleeding in young women. This is not contradictory advice, but only different physiological methods of attaining the same result, namely, the converting of a hyperplastic cystic endometrium into a secretory endometrium which will result in a normal complete menstruation.

The subject is so vast, and new facts are coming to light so rapidly, that it is not possible in a paper of this kind to even attempt to cover the field or review the literature. It is thought that a brief, simplified résumé of the present status of endocrinology, as related to the female sex organs, might be of value at this time, together with the author's experience with some of these hormones.

Let us briefly review the normal physiology as developed in laboratory animals. It is generally believed that the pituitary gland is the so-called master gland of the body, and that most of the other glands of internal secretion are somewhat dependent upon it for stimulation. In this paper we will consider only the anterior lobe of the pituitary and its functions. It elaborates four main hormones, thyrotropic, parathyrotropic, adrenotropic, and gonadotropic. We will limit our discussion to the gonadotropic hormones, as these regulate ovarian function.

The function of the ovary is controlled by two distinct hormones elaborated by the anterior pituitary, the follicle stimulating, and the corpus luteum stimulating. The follicle in turn forms the estrogenic hormone, which causes regeneration of the endometrium and its growth into the so-called proliferative state of development, after which the follicle ruptures and ovulation takes place. The endometrium is greatly thickened and the glands become elongated. However, this hormone alone does not cause full development of the endometrium to the point where implantation of the fertilized ovum can occur. The effect of progesterone, which is elaborated from the corpus luteum, is needed to bring the endometrium to the premenstrual or secretory phase, preparing it for nidation of the fertilized ovum. If the ovum is not fertilized it dies, the corpus

*Read before the Northern Minnesota Medical Association, Duluth, July 19-20, 1940.

luteum degenerates, progesterone is withdrawn, and the endometrium breaks down and is expelled from the uterus with bleeding.

In derangements of the endocrine balance there may be various combinations. The follicle may not receive enough stimulation from the pituitary to become mature and rupture. If it fails to rupture, it continues its effects on the endometrium, and cystic degeneration occurs in the endometrium, functional bleeding takes place, and because it fails to ovulate no corpus luteum develops. Therefore, no progesterone is formed to carry the endometrium through to its pregravid stage. Breaks may occur anywhere along the line, and the hormones are used to attempt to repair these breaks.

We have for practical purposes four different hormones which react well in experimental animals and some of which are of value chinically. These four are: (1) follicle stimulating, (2) corpus luteum stimulating, (3) estrogenic, from the follicle, (4) progesterone, from the corpus luteum, the first two coming from the pituitary and the last two from the ovary. Estrin and progesterone do not stimulate the ovary at all; they only stimulate the endometrium. They are purely substitutive in character and not gonadotropic.

The follicle stimulating gonadotropic hormone is obtained from the pituitary gland of animals, and it has a very slight luteinizing effect also. While this preparation is effective when used on laboratory animals, the results in clinical work have been disappointing. The preparations are unstable and soon lose their potency[2]. Perhaps when a more potent preparation is available the results will improve.

The corpus luteum stimulating hormone is obtained from the urine of pregnant women. It also stimulates follicle development to a slight degree. This is called chorionic gonadotropic hormone because of the association with chorionic villi of pregnancy, where it is elaborated. This is available commercially as Antuitrin "S," Follutein, A. P. L., Antophysin, et cetera. It is an anterior pituitary-like substance and differs from that obtained from the pituitary gland. This hormone also, while it works well in animal experimentation, has a rather limited field of usefulness in practice, and results have varied widely in the hands of different workers.

Theoretically, it should be used in functional bleedings, particularly near puberty, in an attempt to stimulate corpus luteum formation, so that sufficient progesterone will be formed to carry the hyperplastic endometrium on to the premenstrual phase. According to Mazer and Goldstein, endometrial cystosis and hyperplasia always occur together. Abnormal bleeding occurs in advanced stages of hyperplasia when localized areas of necrosis and dilated veins are present in the superficial layers of the endrometrium. They believe that the hyperplasia is caused by a too long continued stimulation by the un-antagonized follicle or estrogenic hormone, rather than by an excessive amount, and that the absence of progesterone is the factor which permits the abnormal continuation of the action of the estrogenic hormone. Emil Novak[5] says that the most frequent variety of functional bleeding is that due to failure of rupture of the follicle with ovulation, and functional persistance of the unruptured follicle for a variable time.

These anterior pituitary-like substances have never been shown to have caused ovulation in the human. In my experience, the results obtained have been very disappointing in most cases, and have not been any better than those obtained by other means before the advent of these substances.

Equine gonadotropic chorionic hormone is obtained from the blood serum of pregnant mares. It is different from the two previous substances discussed; it contains both follicle stimulating and corpus luteum stimulating factors. It is the only hormone, with which I am familiar, which will cause maturation of the ovum and rupture of the follicle in the human.

The indication for its use is failure of ovulation, which is probably fairly common, and it must be remembered that the corpus luteum cannot develop unless ovulation occurs. Therefore, it should be useful in sterility due to failure of ovulation, and also in functional bleeding due to prolonged action of estrin on the endometrium, which in turn is caused by failure of ovulation and the failure of the corpus luteum to develop and control the action of estrin.

In my experience, this material is far superior to the other gonadotropic hormones. I have had two successes in sterility with this substance. They were both one-child sterilities of four and

five years, respectively. The tubes were patent and the menses fairly regular. The other hormones had been used intensively with no result. The material, Gonadogen, was given in one large dose of sixty units on the twelfth day of the cycle and pregnancy promptly ensued. One patient was delivered last month and the other is in her third month of a normal pregnancy. No endometrial biopsies were made in these cases, but they were probably instances of failure of ovulation. I have had fair success in a small series of cases of functional bleeding. I have discarded the other gonadotropic hormones almost entirely in favor of this material. The only drawback is the expense.

We now come to the two ovarian hormones, the follicle, or estrogenic, and the corpus luteum, or progesterone. They have no effect on the ovary itself; they are used clinically to make up for ovarian deficiency. Estrogen controls endometrial development, a deficiency prevents normal regeneration after menstruation, this hypoplasia may result in scanty menstruation or in amenorrhea. It also tends to counteract or inhibit the effect of the anterior pituitary hormone. It is probably the unapposed action of the anterior pituitary hormone, which causes the unpleasant symptoms of the menopause, and so the administration of estrogen gives symptomatic relief. It is most valuable for menopausal symptoms; it is also good in the treatment of gonorrheal vaginitis in children, and in senile vaginitis. It produces its effect in both instances by causing the vaginal mucosa to become thickened and cornified, approaching the adult type of mucosa found during sexual maturity, thus making it more resistant to infection and irritation.

Estrogenic hormone is probably harmful in functional bleeding due to hyperplasia and cystic degeneration. The lack of progesterone is the trouble here. It is valueless in amenorrhea unless there is a true endometrial hypoplasia present. An endometrial biopsy will determine this. Estrin combats uterine hypoplasia and renders the uterus receptive to whatever ovarian function remains, or may be induced by treatment with thyroid or gonadotropic substances, and so may be of value in sterility due to uterine hypoplasia.

There has been some mention in the literature of the danger of encouraging the development of carcinoma by long continued treatment with this hormone. Zondek[8] gave enormous doses up to 1,200,000 rat units to women over long periods, and is of the opinion that there is no danger of carcinoma. He produced great cystic hyperplasia and erosions of the cervix, but no carcinoma. Neither follicles nor corpus luteum developed, and no gonadotropic hormone was released from the pituitary. This also occurs during pregnancy. The large amounts of estrogen present during pregnancy is what prevents new follicles from developing, due to its inhibitory action on the anterior pituitary. Geist and Salmon[1] are also convinced of the freedom from danger of carcinoma.

At the present time there is great confusion in the matter of units of dosage. The international unit is a weight unit, and equals one-tenth of a microgram of estrone. There are several estrogens of different chemical composition and purity. It is thought by most workers that the estrogens should be measured by their effects on spayed rats rather than by weight, and they believe that the rat unit should be used. One rat unit of estrone equals five international units of estrone, but this proportion does not hold good in the case of estradiol and other estrogens of different chemical compositions.

It is estimated that the human female needs 500 Rat Units (2,500 International Units) as purely maintenance dosage, but where there has been a total lack of estrogen for some time, as in the castrate or menopausal woman, the minimal amount of estrogen which will cause the atrophic endometrium to proliferate is 50,000 Rat Units a month, or 1,750 daily for one month. Mazer and Israel[4] advise 10,000 Rat Units (50,000 International Units) every fourth day with gradual reduction of dosage. Often smaller doses will give symptomatic relief at the menopause.

Progesterone is used in the treatment of functional bleeding; it carries the hyperplastic endometrium over into the menstrual stage. It is purely substitutive and does not correct the ovarian dysfunction, which is responsible. It may well be combined with the A. P. L. chorionic gonadotropic hormone, or that from mares' serum. Before progesterone can produce its effect, the endometrium must have first been under the influence of estrogen.

Progesterone also tends to prevent uterine contractions induced by estrin or pituitrin, while estrin makes the uterus more susceptible to contractions induced by pituitrin. For this reason progesterone is valuable in early threatened abortion. I have had good results in this condition. It has been advocated in the treatment of pernicious vomiting and dysmenorrhea. I cannot report any specific cures in these conditions.

Before closing I would like to mention endometrial biopsies. There is no question but that this method is the scientific way to study the different phases of endometrial development and its response to hormone therapy. However, it needs a trained technician to prepare the slides and the procedure is not wholly without danger. Randall[7] has shown that the findings are not always conclusive, and that functional bleeding may occur in almost any phase of the endometrium. This has also been my experience. It probably has its greatest value in studies of sterility in an attempt to determine whether or not the patient ovulates. In a small experience with endometrial biopsies, I have not been greatly impressed with their practical value.

In conclusion: (1) In the author's experience from a clinical standpoint, the gonadotropic hormones obtained from the pituitary glands of animals and from the urine of pregnant women have been of very little value. (2) The gonadotropic hormones obtained from the urine of pregnant mares show great promise. (3) The estrogenic hormone is the most constant and dependable of all the hormones. (4) Endometrial biopsies have not enough practical value to justify the additional trouble, expense and slight danger involved in their use.

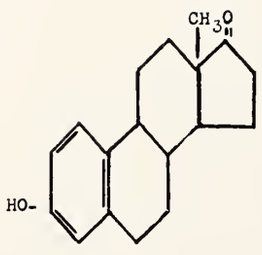
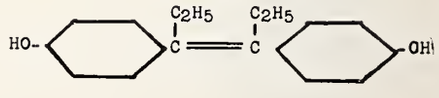
DIETHYLSTILBOESTROL: A SYNTHETIC ESTROGENIC HORMONE



MAX H. HOFFMAN, M.D.

Saint Paul, Minnesota



THE natural estrogenic hormones, estrone and estradiol, lose 95 per cent of their activity when administered orally. Estriol, also a natural occurring hormone, is more active orally than the other two, but at best is not a very effective substance. These estrogenic hormones together with the other sex hormones possess a pentenophenanthrene nucleus in their chemical structure.

In 1938 Dodds and his co-workers synthesized a substance that had the formula ($C_{18}H_{12}O_2$) 4:4 Dihydroxy Alpha: Beta Diethylstilbin, an entirely different chemical structure from the natural occurring hormone. This substance was found to be very active when administered orally and had the additional advantage of cheapness in manufacture.

Experimental studies on animals and humans showed that it was capable of producing all the biological effects of natural estrogens. It was active in producing proliferative changes in the endometrium; it caused withdrawal bleeding and

ESTRONE

DIETHYLSTILBOESTROL

would reduce the excretion of gonadotropic hormones after castration.

Both in the human and in animal experimentation stilboestrol was found to have some very

definite side effects. In rats it produced epistaxis, vaginal and intestinal bleeding. It also produced fatty degeneration of the liver and enlargement of the adrenal gland. In doses of 0.5 to 1 mg. it produced death in mice, and in doses of 5 mg. daily for twenty-five to fifty days it caused disturbances in the myelogenic tissue in dogs. Although the toxic effects appeared to be very definite it must be remembered that the doses were proportionately larger than the amount of the substance used clinically.

TABLE I

Diagnosis	No. of Cases	Therapeutic Results			Treatment with Stilboestrol
		Excellent	Good	Poor*	
Menopause Spontaneous	20	10	3	7	0.1 mg. tid up to 2.0 mg. daily
Menopause X-Ray	1			1	1 mg. daily, 40 days
Menopause Surgical	4	3		1	1 mg. daily 20 – 40 days
Amenorrhea	2	1		1	3 mg. daily 30 days 1 mg. daily 20 days
Acromegaly	2		1	?	3 – 8 mg. daily Total 519 mg. in 5 months
Mastopathy	2	1	1		0.3 mg. daily 7 days
Diabetes Insipidus	1			1	1 mg. 2 days
Migraine	2	1	1		1 mg. daily 10 days
Total	34	16	6	12	

*Of the twelve patients included under poor results seven suffered with reactions and did not receive sufficient medication.

Considerable literature is now available reporting clinical studies. Several very severe reactions have been noted, but no fatal cases are on record. The toxic effects appear to be quite temporary. The percentage of unfavorable reactions vary greatly among the different investigators, the figures running from 3 to 60 per cent.

Most of the toxic reactions appear as nausea and vomiting, diarrhea, restlessness, skin eruptions, toxic psychosis, parethesias and thirst. Clinical studies have failed to show any definite evidence of renal, hepatic or myelogenic tissue changes. The reactions were often so slight that the administration of the hormone could be continued.

Stilboestrol has shown itself to be a very active estrogen when taken orally. It apparently is almost as active by mouth as it is by injection. It is fifteen to twenty times as active orally as estrone. However, it is only a fourth to a third as active intramuscularly as estradiol benzonate and much less active than the new partial synthetic estrogen ethinyl estradiol.

In all probability its oral activity depends on the inability of the liver to change or inactivate this substance in the manner in which the natural estrogens are altered. This inactivating mechanism in the liver is believed to be necessary to prevent a harmful accumulation of estrogens in the body. For that reason it is believed by some that the administration of an estrogen resistant to the liver may be deleterious.

This report is based on observations made in thirty-four cases in which stilboestrol was administered. In all cases careful urine, hemoglobin and leukocyte count determinations were made at intervals. No other laboratory tests were made, except that in some instances urinary sex hormone excretion studies were determined, but these values will not be included in this report.

The amount of diethylstilboestrol given varied greatly in the individual cases. In the menopause group, no patient received more than 2 mg. daily,

whereas the majority of these patients received one mg. daily. In several instances satisfactory results were achieved with 0.3 mg. a day.

TABLE II. REACTIONS TO MEDICATION

Group	Type of Reaction	No. of Cases	Percentage
I*	Severe reactions	7	20.6
II	Mild reactions	3	8.9
III	Reaction to oral, but not to hypodermic	1	2.9

*The reactions under Group I required cessation of medication. In cases under Groups II and III medication was continued.

Two young females with amenorrhea were observed. In one case 3 mg. daily for thirty days produced a rhythmic menstrual flow that lasted for four periods; the other patient received 1 mg. daily for twenty days with no effect. Diethylstilboestrol was given to two individuals with acromegaly with the hope that large amounts of estrogenic hormone would inhibit the pituitary activity. One patient received at various intervals 3 to 8 mg. a day over a period of five months, taking a total of 519 mg. The other patient with acromegaly was not followed long enough to make any observation that would be of value. Two cases of mastopathy in young girls who had most of their trouble around the menstrual period were given 0.1 of a mg. three times a day for seven days preceding the onset of the period. The single patient with diabetes insipidus after taking 1 mg. a day for two days developed a very unfavorable reaction and was forced to stop the medication. The two individuals with migraine that occurred around the menstrual period were given 1 mg. daily for ten days before the onset of the period.

It appears that in some cases there is a very definite relationship between the size of the dose and the development of disagreeable reactions, although several individuals developed unfavorable side effects on 0.3 mg. daily. It was noticed frequently that on raising the dose above 1 mg. a day the patient became nauseated, and on reducing the dose to one mg. or less a day the nausea disappeared. The majority of the patients, however, could take apparently any size of dose without any disturbance. In my group five patients had nausea, and in two of these it was severe enough to cause vomiting. Two patients had a peculiar full sensation in the head, and two others complained of lassitude. Three patients complained of tightness in the throat that caused a feeling of suffocation. This type of reaction, as far as I know, has not previously been reported.

The therapeutic results in the menopausal group as a whole appeared to be excellent, and those able to take a sufficient amount of the hormone had an improvement comparable to those who received an adequate amount of the natural estrogen by hypodermic injection. Of the twenty-five cases of menopause, sixteen were either completely or almost completely relieved of their symptoms. Of the nine cases grouped under the heading "poor results," four were unable to take a sufficient amount of the hormone and five did not improve even with a sufficient dosage.

Of the two cases of amenorrhea, one result was good with 3 mg. daily for thirty days; the other result was not good, but this patient received only 1 mg. daily for twenty days. This was probably due to an insufficient amount of the hormone. The middle-aged woman with acromegaly who received 519 mg. of stilboestrol in a period of five months had some very definite effects. The headaches were lessened, the voice was improved and the soft tissue and particularly the width of the nose was definitely improved. This result might be due to reducing the activity of the pituitary gland or to the feminizing influence of the hormone. The result was not sufficiently satisfactory to eliminate the necessity of further therapy of another type such as x-ray. The second patient with acromegaly was not followed long enough to form a definite opinion.

The two patients grouped under the heading of migraine had their attacks around the menstrual period and both were benefited considerably by the medication. In the group of spontaneous menopause there were also several who had migraine and who received benefit from this therapy.

A great deal has been written both for and against the clinical use of diethylstilboestrol. Its advantage, of course, lies in the fact that it is active orally, and, in my experience, dose for dose, it is as active orally as the natural hormones are by injection. It had, in my group, the disadvantage of producing in at least 20 per cent of the cases reactions so disagreeable to the pa-

tient that they would prefer to have their symptoms rather than medication. There is no good evidence that in the doses used clinically there occurred any permanent injury to the tissues of the body. Inasmuch as relatively small doses are often effective in relieving symptoms, and that the size of the dose is often responsible for the production of unfavorable by-effects, one should start with doses of not more than 0.1 mg. three times a day, gradually increasing this dose until either the desired effect is obtained or until the patient becomes uncomfortable from the medication.

It seems that where the cost of medication is important, and in those individuals who do not tolerate hypodermic injections, diethylstilboestrol offers a very valuable addition to our hormone therapy.

NOTE: Since the presentation of this paper before the Minnesota Society of Internal Medicine, in June, 1940, at Duluth, Minnesota, the number of cases treated with this preparation has been in the neighborhood of one hundred with essentially the same results. The diethylstilboestrol used in this study was furnished through the kindness of the Winthrop Chemical Company, Inc., and the Abbott Laboratories. No difference was noted between the preparations furnished by these two companies.

THE DIAGNOSIS OF PANCREATITIS*

MANDRED W. COMFORT, M.D.

Rochester, Minnesota

THE diagnosis of pancreatitis and, to a lesser extent, the diagnosis of malignant lesions of the pancreas have been a surgical rather than a medical problem. This is not a matter for wonder when one considers the situtation of the pancreas deep in the abdomen, its inaccessibility to palpation, the ability of diseases of the pancreas to mimic disease of other organs in the upper part of the abdomen, and the lack of accurate laboratory procedures for the diagnosis of pancreatic disease. However, this situation is undergoing a change, and the diagnosis of pancreatic disease pre-operatively is being made with increasing frequency. The change may be attributed to the development of laboratory methods of diagnosis and the increased awareness of pancreatic disease that the use of such tests has brought about.

Acute Pancreatitis

Interest in acute pancreatitis has been directed almost entirely to the more severe grades of the disease, such as pancreatic necrosis. The mild forms of acute pancreatitis have been ignored until the last few years. Pancreatic necrosis is a rare disease and important largely because of its high mortality. The mild degrees of pancreatitis, on the other hand, occur frequently and are important because of their effect on the postoperative convalescence, because they may terminate in pancreatic necrosis and because they may become chronic and produce persistent disturbances of pancreatic function. Both the mild and severe degrees of pancreatitis may be diagnosed pre-operatively if the condition is suspected clinically, if the clinical data are carefully weighed and if simple laboratory aids are utilized. Some of the problems involved in the diagnosis and the clinical and laboratory data useful in reaching a pre-operative diagnosis of acute pancreatitis are illustrated by the following case.

Case 1.—A woman, aged thirty-eight years, registered at the Mayo Clinic May 18, 1937. She stated that recurrent attacks of epigastric colic, severe enough to require morphine for relief, had begun in 1929. These attacks at first had occurred once every six months but recently they had occurred as often as every two months. A very severe attack associated with nausea, vomiting, chills, fever and jaundice had taken place in March, 1937. Minor attacks had occurred frequently since that time; a severe attack had begun four days prior to her registration at the Mayo Clinic.

Examination disclosed a slight icteric tint to the skin and sclera and slight tenderness and rigidity in the right upper quadrant of the abdomen. Urinalysis did not disclose any abnormality. The value for the hemoglobin was 13.8 gm. per 100 c.c. of blood. The leukocyte count was 15,700 per cubic millimeter of blood and 93.5 per cent of the leukocytes were neutrophils. The concentration of bilirubin in the serum was 1.6 mg. per 100 c.c. and the van den Bergh reaction was direct. The activity of lipase in the serum, expressed in terms of cubic centimeters of twentieth-

*From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Read at the meeting of the Southern Minnesota Medical Association, Red Wing, Minnesota, September 23, 1940.

normal solution of sodium hydroxide, was 5.3. The value for the serum amylase was 1,500 units. The diagnosis was chronic cholecystitis with stones, acute pancreatitis and possibly a stone in the common bile duct. Exploratory laparotomy, which was performed on May 21, 1937, confirmed the clinical diagnosis of cholecystitis, gallstones and acute pancreatitis. Cholecystectomy was performed for subacute cholecystitis with cholelithiasis. The pancreatitis was graded 2, on the basis of 1 to 4, by the surgeon. Exploratory choledochostomy did not disclose stones and the scoop could be passed through the lower end of the common bile duct and into the duodenum without encountering resistance.

Acute pancreatitis or some complication of cholecystic disease such as pancreatitis may be suspected when an attack of biliary pain is prolonged, when the attack recurs frequently, if not daily and is associated with persisting tenderness in the right upper quadrant of the abdomen and in the epigastrium. Pancreatitis may also be suspected when the pain is not relieved by the administration of morphine. Pancreatitis is almost certain to be present when the pain and tenderness spread to or involve the left side of the epigastrium and especially so if the pain extends to and tenderness develops in the left subcapsular region. In case 1 it was the frequently repeated attacks of pain which suggested the possibility of acute pancreatitis and led to the determination of the concentrations of amylase and lipase in the blood serum. The presence of a stone in the common bile duct was suggested by the history of jaundice which in this case must have been due either to cholangitis or an associated hepatitis.

The diagnosis of acute pancreatitis may be established with great accuracy by the determination of values for lipase and amylase in the serum.[4,5,6] These values rise above the normal of 1.5 c.c. of twentieth-normal solution of sodium hydroxide for lipase in the serum and 320 units for amylase in the serum within a few hours after the onset of the acute episode. The maximal increase is reached within twelve to twenty-four hours and the values then decline. The value for the amylase usually reaches normal within three to four days and that for lipase usually becomes normal in seven to fourteen days. If positive findings are to be expected with any great regularity, values must be determined early in the course of the disease. The concentration of lipase in the serum has so far been accurate in pointing to the presence or absence of active pancreatic inflammation in 99 per cent of cases and the concentration of amylase has been an accurate indication of the condition of the pancreas in 87 per cent of cases in which it has been possible to determine the status of the pancreas in the light of both clinical data and the description of the pancreas as given by the surgeon.[1] The values for amylase and lipase in the serum will be elevated in the more severe degrees of acute pancreatitis (pancreatic necrosis) so long as functioning pancreatic tissue remains.

Disturbances of carbohydrate metabolism occur in cases of acute pancreatitis but are usually transitory. Glycosuria has been reported in from 5 to 20 per cent of cases.[2,8,9,10] Hyperglycemia has been reported in from 50 to 100 per cent of cases[3,7,10] but because this condition also occurs in association with other acute diseases of the upper part of the abdomen and with coronary thrombosis, a concentration of less than 175 mg. of sugar per 100 c.c. of blood should be interpreted with a great deal of caution. If pre-existing diabetes can be excluded, glycosuria and hyperglycemia should point definitely to inflammatory disease of the pancreas if found during attacks of pain in the upper part of the abdomen. Tests for tolerance for dextrose may sometimes need to be performed in order to demonstrate the milder degrees of dysfunction of the islands of Langerhans which occur as a result of acute pancreatic inflammation.

Disturbances of the external secretion of the pancreas sometimes persist after disturbances of internal secretion have disappeared. They may be detected by study of the duodenal contents after stimulation with either secretin or mecholyl (acetyl-beta-methylcholine chloride). These methods of study will be considered subsequently.

Chronic Pancreatitis

Chronic pancreatitis to most physicians has usually meant the combination of steatorrhea and diabetes mellitus but these manifestations usually occur when the pancreatitis is severe. In cases in which the disease is mild it must be recognized by manifestations that are less marked than steatorrhea and diabetes mellitus. In its early stages chronic pancreatitis is manifested by repeated attacks of epigastric pain and tenderness, by disturbance of the motility of the stomach and intestine, and by jaundice produced by

pressure of the swollen head of the pancreas on the common bile duct. In cases in which the pancreatitis is severe, diabetes mellitus, diarrhea (either with or without steatorrhea), pancreatic calcification, fatty metamorphosis of the liver, hepatic decompensation with ascites may develop and loss of weight and even emaciation may occur. Chronic pancreatitis may or may not be associated with disease of the biliary tract. Chronic pancreatitis secondary to disease of the biliary tract may be suspected when disturbance of pancreatic function occurs during the course of cholecystic disease and whenever repeated attacks of colic occur following cholecystectomy.

Case 2.—A woman, aged forty-five years, registered at the Mayo Clinic July 16, 1934. In 1917 appendectomy and cholecystostomy had been performed for attacks of epigastric pain typical of biliary colic. In 1918 cholecystectomy had been necessary for relief of pain. In 1920, epigastric distress and pain, which usually had been induced by fat and fried foods, again had been noticed. The pain had been mild until eight months prior to her registration. During the eight months, the pain had become more severe and the patient had had five attacks of epigastric colic severe enough to require hypodermic injections of morphine for relief. The stools had been acholic during the attacks. The results of physical examination were essentially negative. Roentgenograms of the spinal column and stomach did not disclose any abnormality. The bromsulfalein test of hepatic function did not disclose any retention of dye. The concentration of bilirubin in the serum was 1.0 mg. per 100 c.c. and the van den Berg reaction was indirect. The activity of lipase in the serum in terms of twentieth-normal solution of sodium hydroxide was 1.7 c.c.

The diagnosis was not clear-cut; however, it was thought that cholangitis or a stone in the common bile duct was the most probable cause of the symptoms. The diagnosis of pancreatitis was considered. On July 27, 1934, exploratory laparotomy was carried out. The common bile duct was found to be 2 cm. in diameter but its walls were not thickened and were normal in color. The duct was opened and obstruction was met with in the region of the sphincter of Oddi and in the region of the pancreatic portion of the duct. Scoops were passed through the ampulla into the duodenum with difficulty. The pancreas itself was enlarged and nodular, and severe pancreatitis was present. A T tube was inserted in the common bile duct and left in place for three months. On August 19, 1934, cholangiography revealed the constriction of the common bile duct at its point of entrance into the duodenum. Ninety per cent relief of symptoms was obtained.

The diagnosis of pancreatitis was not made pre-operatively in this case. Pancreatitis was suspected, however, with stone in the common bile duct and stone in the stump of the cystic duct because of the history of recurring colic after cholecystectomy. Clinical manifestations did not point clearly to pancreatic disease; the value for the serum lipase was slightly elevated but this finding was ignored because of the small degree of elevation and because the test was new at that time and its reliability had not been established.

Pancreatitis unassociated with disease of the gall bladder or bile ducts is illustrated by the following case.

Case 3.—A man, aged fifty-six years, registered at the clinic August 5, 1940. He had been perfectly well until April 1, 1940. Severe, almost constant, pain and severe tenderness had been present in the right upper quadrant of the abdomen almost constantly from April 1 to 10. The severity of the pain had decreased but distress had occurred almost daily. The distress had seemed to spread to the left upper quadrant of the abdomen and across the back at the level of the costovertebral angles. It had been intensified by meals, particularly by heavy meals eaten at noon or at night. Urinalysis had not revealed any abnormality. On May 1, the daily number of stools had increased from three to five. Defecation usually had occurred with marked urgency about fifteen minutes after meals. After defecation the patient had observed droplets of fat floating on the water in the toilet. Another severe attack of pain had occurred on July 1. At this time the pain had been situated in the left upper quadrant of the abdomen. The pain had lasted for several days and had been associated with marked soreness; it had been followed by polyuria, polydipsia and polyphagia. His weight had decreased from 145 pounds (65.8 kg.) to 112 pounds (50.8 kg.).

Physical examination at the clinic disclosed that the liver could be palpated about 8 cm. below the costal margin on inspiration. The reaction of the urine was acid and the specific gravity was 1.035. Glycosuria was present; the urine contained 6 per cent of sugar. Acetone and diacetic acid were not present in the urine. Examination of the blood revealed that the concentration of hemoglobin was 13.5 gm. per 100 c.c. The leukocyte count was 12,700 per cubic millimeter. The concentration of sugar in the blood was 265 mg. per 100 c.c. The results of routine serologic tests for syphilis were negative. Analysis of the gastric contents revealed that the values for the total acidity and the free hydrochloric acid were 34 and 20 respectively according to the method of Töpfer. Examination of the stools revealed an excess of oil or fat. Roentgenologic examination of the thorax, gall bladder, stomach, terminal portion of the ileum, and the colon did not disclose any abnormality.

The patient was admitted to the hospital on August 10. His temperature and pulse rate remained normal. Further study of the blood including mor-

phologic study of the erythrocytes, did not disclose any abnormality. The concentration of bilirubin in the serum was 1.3 mg. per 100 c.c. and the van den Bergh reaction was indirect. The bromosulfalein test for liver function revealed retention of dye, grade 1. The concentrations of amylase and lipase were 106 units and 0.1 c.c. of twentieth-normal solution of sodium hydroxide, respectively. Fat made up 60.4 per cent of the dried stools. Studies of the external pancreatic secretion after stimulation with secretin showed marked diminution in the secretion of fluid, carbonate and the enzymes, amylase, trypsin and lipase.

He was given a diet containing 346 gm. of carbohydrate, 105 gm. of protein and 54 gm. of fat, in order to control the diarrhea. Glycosuria persisted in spite of the administration of 6 units of protamine insulin and 10 to 24 units of regular insulin daily.

The diagnosis was chronic pancreatitis and a disturbance of the internal and external secretions of the pancreas (diabetes mellitus and steatorrhea). Exploratory laparotomy was performed August 23. The head of the pancreas was found to be two or three times its normal size and to be the site of brawny induration; the body and tail of the pancreas were cylindrical. The organ was approximately 3.5 cm. in diameter, and its length was normal. The gallbladder and common bile duct were distended; however, the wall of the gall bladder was normal in color. The gall bladder was incised but no stones were found. Cholecystostomy was performed and a tube was inserted into the gall bladder. The liver appeared to be in normal condition.

The diabetes improved markedly and at the time of the patient's dismissal from the hospital on September 10 he was taking only 6 units of protamine insulin daily and his diet contained 346 gm. of carbohydrate, 145 gm. of protein and 69 gm. of fat. Glycosuria was not present and the concentration of blood sugar was 125 mg. per 100 c.c. on August 30. He was returned to his home on September 13 and was instructed to increase the intake of fat if there was no further trouble with diarrhea.

In this case the gall bladder, stomach and colon were excluded roentgenologically as the site of the disease process. The site of the pain and tenderness in the left upper quadrant of the abdomen, as well as the development of steatorrhea following the first attack and diabetes mellitus following the second acute attack, pointed with certainty to the diagnosis of pancreatic disease. Various laboratory studies proved that disturbance of pancreatic function was widespread.

In cases of chronic pancreatitis, elevations in the concentrations of lipase and amylase in the serum may persist between attacks and long after major and minor attacks have ceased. The concentration of amylase rarely is increased for prolonged periods. In this case, five weeks had passed since the last really severe attack and the values for amylase and lipase in the serum had returned to normal. Disturbances of carbohydrate metabolism may not be so marked as in this case and sometimes may be detected only by a diabetic type of blood sugar curve following the administration of dextrose. A very significant point about the diabetes in this case was its absence in the early stages and its development in the later stages of the disease. Study of the external pancreatic secretion may alone demonstrate that pancreatic disease is the cause of the attacks of pain after the acute inflammation has ceased. The duodenal contents are quantitatively collected after stimulation with either purified secretin or mecholyl.[5,6] Secretin is administered in doses of 1 clinical unit per kilogram of body weight. Fifteen milligrams of mecholyl administered subcutaneously stimulates external pancreatic secretion satisfactorily. The duodenal contents are most accurately removed by continuous suction through the double-barreled gastroduodenal tube devised by Agren and Lagerlöf.[1] By means of one barrel of this tube the gastric contents can be aspirated and thus prevented from entering the duodenal cavity and confusing the results of analysis of the duodenal contents. A negative pressure of 16 inches (40.6 cm.) of water has been found satisfactory. The duodenal contents are measured in cubic centimeters and the concentration and total secretion of carbonate and of amylase, lipase and trypsin per unit of time are determined and compared with values obtained for normal individuals. The importance of measuring the volume of duodenal contents obtained and of determining the total secretion of enzymes (concentration per cubic centimeter multiplied by the number of cubic centimeters of duodenal content obtained per unit of time) as well as the concentration of enzymes is well illustrated by data obtained in a case of chronic pancreatitis and shown in Figures 1 and 2. The low concentration of trypsin cannot be interpreted to mean diminished secretion of trypsin, for the total secretion per unit of time shows that trypsin is being secreted in amounts above normal. In Case 3 all of the fractions of the external secretion of the pancreas were disturbed. In some cases, however, secretion of amylase alone may be disturbed and this probably represents the

mildest degree of pancreatic injury. The decrease in the volume of duodenal contents and in the carbonate content seem to occur in the ease in the pancreas. According to Thaysen, only when 35 to 40 per cent or more of ingested fat is lost as neutral fat does a form of steator-

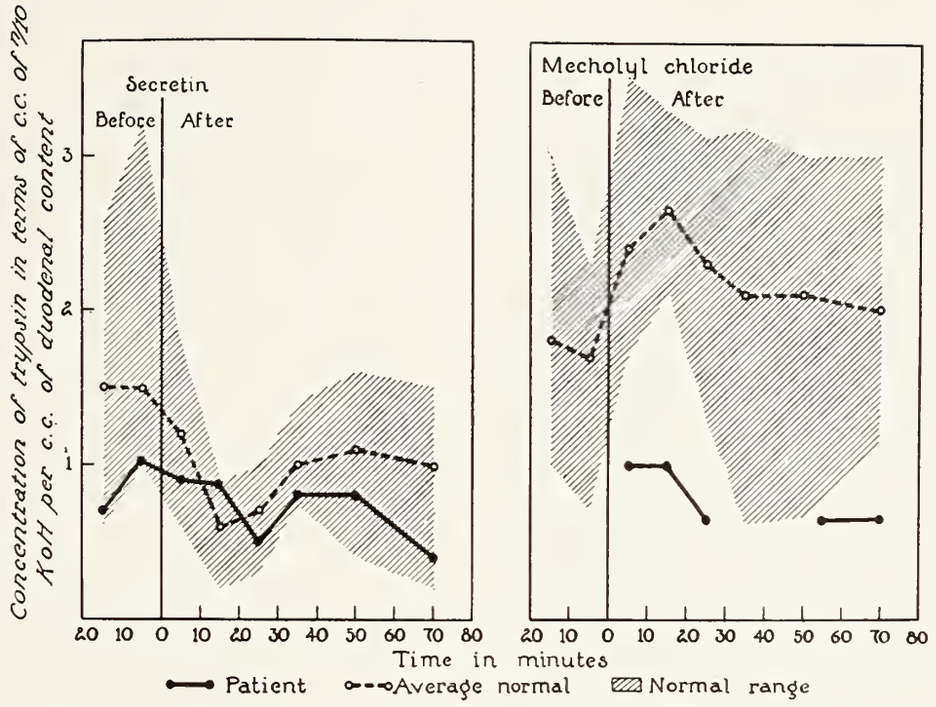


Fig. 1. The concentration of trypsin in the duodenal contents in a case of chronic pancreatitis is compared with the concentration in the duodenal contents of normal persons. The concentration of trypsin after stimulation with secretin in this case appears in the lower range of values found for normal persons but is definitely below this range after stimulation with mecholyl. The low concentrations do not mean abnormally low secretion but are due to the diluting effect of hypersecretion of fluid by the pancreas.

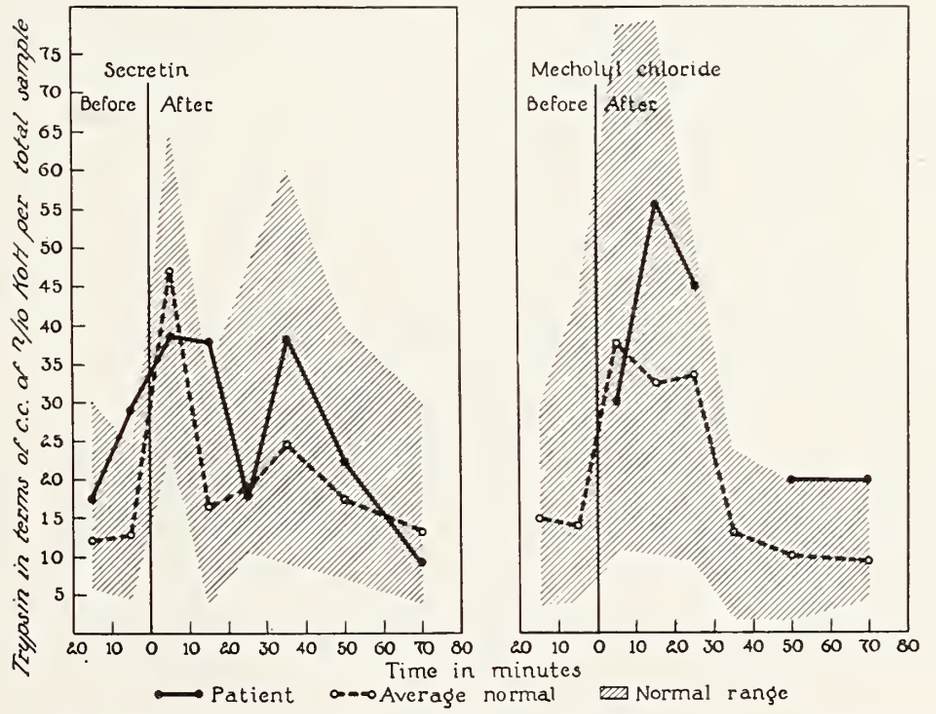

Fig. 2. The total secretion of trypsin in a case of chronic pancreatitis is compared with the total secretion of trypsin per unit of time by normal persons. A secretion of trypsin is seen after stimulation with both secretin and mecholyl in spite of the low concentrations of trypsin.

more extensive degrees of pancreatic disease.

Examination of the stools for food seldom furnishes information that will localize the disrhea diagnostic of pancreatic disease exist. According to the same author, the loss of more than 3 gm. of nitrogen in the stools per day

will probably distinguish the steatorrhea of pancreatitis from that due to diseases of absorption, such as sprue.

Among the mechanical effects of pancreatitis

Fig. 3. Roentgenogram showing extensive calcification of the head and body of the pancreas.

may be mentioned obstruction of the common bile duct with obstructive jaundice and disturbances of motility of the stomach and small and large intestines. The obstruction of the common bile duct may sometimes be demonstrated, as in Case 2, by cholangiography. Hypomotility of the gastro-intestinal tract may be marked. Retention of barium in the stomach for as long as twenty-four hours has been noted, as well as marked hypomotility of the bowel. The hypomotility at times may be due to actual ileus, which often is localized, and may lead to the erroneous diagnosis of intestinal obstruction. Pancreatic calcification (Fig. 3) may be demonstrated by special roentgenograms of the pancreas; when present it is bona fide evidence of previous or existing chronic pancreatitis. Fatty metamorphosis of the liver may be detected by the bromsulfalein test.

EXTRAPLEURAL PNEUMOTHORAX*

G. A. HEDBERG, M.D.
Nopeming, Minnesota

IN the treatment of pulmonary tuberculosis the extensive use of collapse therapy has been the major factor in improving the prognosis of patients entering the sanatorium with advanced and destructive lesions. Extrapleural pneumothorax has recently been added to the various surgical procedures used to collapse diseased lung in cases where intrapleural pneumothorax could not be induced. This procedure consists of stripping the lung, together with both layers of pleura, from the thoracic wall and mediastinum, thereby creating a space which is maintained by air injections. The purpose of this paper is to present the results of our small series of cases, to discuss the complications encountered, to describe the operative procedure and aftercare, and to give our impression of the value of this addition to collapse therapy.

Interest in this procedure was initiated by the report of the experiences at the Brompton Hospital for Diseases of the Chest, made by Belsey at

*Revision of original paper presented at meeting of Minnesota Trudeau Medical Society at Duluth, Minnesota, August 24, 1940 to include data to March 1, 1941.

the meeting of the American Association for Thoracic Surgery at Atlanta, Georgia, in 1938, and the interesting discussions following his paper. It was further stimulated by the reports of Overholt and Tubbs, and others which appeared in the literature shortly after this. We have been favorably impressed by Dr. Kinsella's results with the procedure of extrapleural pneumonolysis with the insertion of a paraffin pack. The use of paraffin, however, is limited to relatively small apical lesions. It seemed to us that a successful extrapleural pneumothorax might be the best way of arresting disease and closing cavities in cases in which thoracoplasty would be contraindicated due to extensive or recent involvement of the contralateral lung and in cases too toxic to consider risks for multiple stage thoracoplasty.

The first case of extrapleural pneumonolysis, with subsequent extrapleural pneumothorax, was performed at Nopeming in March 1939. Immediately thereafter, it was my privilege to spend a few days at Madison, Wisconsin, and at the Wisconsin State Sanatorium at Wales, where the results of a series of over fifty cases operated by Dr. Gale were impressive and influenced us in the selection of a small series of cases for this procedure. During the spring of 1939 we operated upon seven additional patients, thereafter waiting 10 months before adding any more cases to our series. In the two years since the first operation was performed at Nopeming Sanatorium, extrapleural pneumonolysis for the production of extrapleural pneumothorax has been done twenty-two times on twenty patients. In addition, the procedure was attempted but abandoned in three cases in which extreme inflammatory reaction made adequate stripping impossible. Bilateral pneumothorax was established in one case, later converted to bilateral extrapleural oleothorax and in one case a secondary pneumonolysis was performed to increase the collapse of the original pneumothorax. We have tried to make this series include as wide a variety of indications as possible from the standpoint of involvement of the lung, toxemia, and other considerations. During this time we have formed certain impressions which will be discussed later in this paper.

In our series of cases, three patients were operated under general inhalation anesthesia (cyclopropane); a combination of local supplemented by inhalation anesthesia was used in eight patients; eight patients were operated under local infiltration anesthesia exclusively; and in the last four consecutive cases intravenous anesthesia (pentothal sodium) was used together with intratracheal administration of oxygen. In one half of the group in which local anesthesia was used, it was necessary to supplement with inhalation anesthesia to completely control pain or cough occurring when the pleura was stripped from the mediastinal structures. Intravenous anesthesia with oxygen inhalation appeals to us as the most satisfactory method for this procedure.

Briefly, the operative procedure for the production of an extrapleural pneumothorax for an apical lesion is similar to that of an upper posterior stage thoracoplasty from the standpoint of surgical approach, duration of the procedure, and the postoperative reaction of the patient. The patient's position is the same as that used for an upper posterior thoracoplasty. The incision is similar but not as extensive in order to reach the costal bed. A segment of the third, fourth, or fifth rib is removed from the posterior angle laterally for a distance of about 10 cm., particular care being taken to strip the periosteum with as little damage as possible and to trim the resulting rib stumps so as to remove all of the rib from which the periosteum has been stripped. Through an incision in the periosteal bed, the extrapleural space is developed by separating the parietal pleura from the endothoracic fascia. The parietal pleura can be peeled along this plane without great difficulty as a rule. Most of the stripping is done with the finger or by careful dissection with a small gauze pledget on the end of a forceps. Occasionally areas of denser adherence may require sharp dissection, but by patient and careful freeing of the lung around these areas, they frequently can be peeled off with the gauze dissecter. The lung is usually freed posteriorly as far as the seventh rib, and anteriorly as far as the second rib, though the lysis may be more or less extensive depending, of course, upon the underlying pathology. It is extremely important that the apex be freed and that the stripping be carried down along the mediastinum below the arch of the aorta on the left and to the azygos vein on the right. Failure to free the apex completely may result in hung, slit-like cavities which remain patent. Bleeding encountered is usually

controlled by packing, though small arteries may be opened which require the use of silver neural clips for hemostasis. This occurs more frequently when the extrafascial plane is accidently entered during the dissection. It is not unusual to inadvertently lose the extrapleural plane and enter either into the extrafascial or into the intrapleural space.

I believe that it is always wise to free more of the lung than one feels is necessary to control the disease, as it is only too easy to allow the lung to re-expand. When sufficient lysis has been performed, the extrapleural space is washed out with normal saline and inspected for persistent bleeders, following which closure is made by continuous suture, using fine chromic gut to close the periosteal incision followed by an overlapping of the intercostal muscle from above and below the resected rib segment. The usual thoracoplasty closure completes the operation. In a few cases we filled the extrapleural space with normal saline solution before closure with the idea of making the first aspiration easier, but have since abandoned this procedure. With one exception, the average duration of the surgical procedure was 2 hours.

The morning following operation, a pneumothorax apparatus is brought to the patient's bedside and a needle is inserted into the extrapleural space via the first interspace, usually in the anterior axillary line. Manometric readings are taken, and enough air is injected to bring the pressures to approximately plus 10 cm. of water. On the second postoperative day the patient is fluoroscoped and brought to the operating room for aspiration and irrigation of the extrapleural space. The needle is inserted in the paravertebral region high in the thoracic cage. Thorough aspiration of the extrapleural space is accomplished without requiring much coöperation from the patient by using the Trendelenburg position and lateral tilt in order to have the fluid gravitate towards the apex where the needle has been inserted. I feel this is safer than attempting to tap the space near the lower border of the lysis where there is a possibility of lung puncture. The fluid, which is quite bloody, is aspirated and the space thoroughly irrigated with normal saline. If bleeding is found to be more than usual, it has been my habit to leave 200 or 300 c.c. of saline in the space, following which the pressures are again adjusted to a maximum positive of approximately 10 cm. of water. In the uncomplicated cases, we have aspirated approximately every other day until the space is dry. In this group the average number of aspirations required has been between three and four.

The reaction of the patient towards the surgical procedure is very similar to that of an upper posterior stage thoracoplasty. With the exception of three cases, the postoperative shock was estimated as slight to moderate. In the series of twenty-two operations, eleven intravenous infusions of saline were given; no transfusions were necessary; and oxygen was not required in any case. The blood pressure usually drops following operation for a matter of a few hours, rapidly returning towards normal. By the next morning the patient is usually able to eat breakfast and is quite comfortable. The duration of temperature and pulse elevation following operation in the uncomplicated cases averaged less than a week.

The success of the extrapleural pneumothorax is dependent more upon proper aftercare than on the surgical procedure itself. For this reason I believe the procedure will only be popular when carried out in a tuberculosis sanatorium or at least where the medical staff is thoroughly familiar with the treatment of complications of pneumothorax. I sincerely believe that the majority of the complications which we encountered would have been prevented if we had started out with the experience which we have since gained in handling this small number of cases. It is significant that six of the nine patients who had any complications whatsoever were in the first group of eight patients operated upon. It is to be realized that every extrapleural pneumothorax starts out complicated with a bloody effusion which later on becomes serous and which is an ideal culture for any contaminant organisms. For this reason vigorous treatment towards the removal of all bloody effusion with the object of obtaining a dry space as soon as possible must be pursued. Aspiration of the bloody effusion alone without thorough irrigation with saline until the fluid returns clear invites the development of postoperative empyema. For the same reason, extreme care should be taken to prevent any possible puncture of the underlying lung. When one follows aspiration of the effusion with thorough irrigation with normal saline, it is not

necessary to thoroughly dry the pleural space as small amounts of normal saline are quickly absorbed in the extrapleural space, leaving a dry pneumothorax. The importance of the saline irrigation has not to my knowledge been stressed in the articles written on this subject. In fact, the postoperative care of the collapsed lung has been passed over rather lightly by most of the writers. Possibly this is due to the fact that the articles have been written by the surgeons who have been overly impressed by the value of their particular part in the procedure, in other words the extrapleural pneumonolysis, and have not realized that the success or failure of the extrapleural pneumothorax has often been due to the judgement and hard work of the staff man in establishing the actual collapse.

In the beginning we tried to follow the advice of the writers regarding pressures. Many of them advocated rapid conversion of the pneumothorax to a high positive pressure type, using pressures of from plus 30 to plus 50 cm. of water. In an early group of patients we tried this method and ran into difficulties. We have since held our pressures down to a maximum of about 10 cm. during the first few weeks of the collapse therapy, later on in some cases increasing the pressures to a maximum of plus 30 cm. of water. We have found that the use of higher pressures is unnecessary, especially if one starts out with a pneumonolysis which has been more than adequate for the disease involved. With this margin to work with, one can allow the lung to gradually re-expand under daily fluoroscopic control during the first few weeks until one considers that the collapse is proper, only then increasing the pressures if necessary. This method is accompanied by practically no complications. If it is impossible to hold the amount of collapse desired, I am of the opinion that conversion to oleothorax is indicated, as this appeals to me as being a more logical procedure than subjecting the collapse to wide variations in pressure, and thereby inviting the return of effusion. We have used oleothorax in order to maintain a collapse in the presence of obliterative pleuritis in intrapleural pneumothorax and have yet to find a reason for considering this treatment unsafe.

For the first six to eight weeks following operation frequent refills should be given, at least twice a week, always preceded by fluoroscopic study. After this period of time, the usual extrapleural pneumothorax becomes well established and the interval of refills can be extended. Following several months of collapse, only small amounts of air are required, and we have found that it is safe to stretch the interval in some cases to as much as three weeks between refills. We have converted seven of the group to oleothorax. This is a very satisfactory procedure for permanently maintaining collapse of the pathology and frees the patient of the necessity of returning for frequent refills.

In the following analysis of this series the complications encountered will be particularly stressed as well as presenting a description of the type of case selected for the procedure and the results following the establishment of extrapleural pneumothorax. From the standpoint of age and sex this group is similar to any group of candidates for thoracoplasty. It consisted of nine women and eleven men, ages ranging from twenty-one to forty-seven. Table I is an attempt to classify the results by the patient's condition, dividing them into three groups according to the condition of the contralateral lung.

TABLE I. EXTRAPLEURAL PNEUMOTHORAX

	Number	Results
Contralateral Lung Negative or Minimal Inactive	*6*	
F.A. pneumonic with cavity	1	Dead
Collapsed lung M.A. with cavity	4	Satisfactory
Minimal progressive	1	Satisfactory
Contralateral Lung Extensive Quiescent or Retrogressive Lesion	*12*	
M.A. with cavity	4	Satisfactory
F.A. with cavity	7	Satisfactory
F.A. with cavity	1	Unimproved
Contralateral Lung Progressive Lesion	*2*	
F.A. with cavity	1	Dead
Collapsed lung M.A. with cavity	1	Satisfactory

*F.A. stands for "far advanced" and M.A. for "moderately advanced."

It will be noted that in twelve patients the contralateral lung was involved by an extensive quiescent or retrogressive lesion which was the main indication for this procedure rather than thoracoplasty. Two of these patients each had two operations, one having a bilateral extrapleural pneumothorax later converted to bilateral

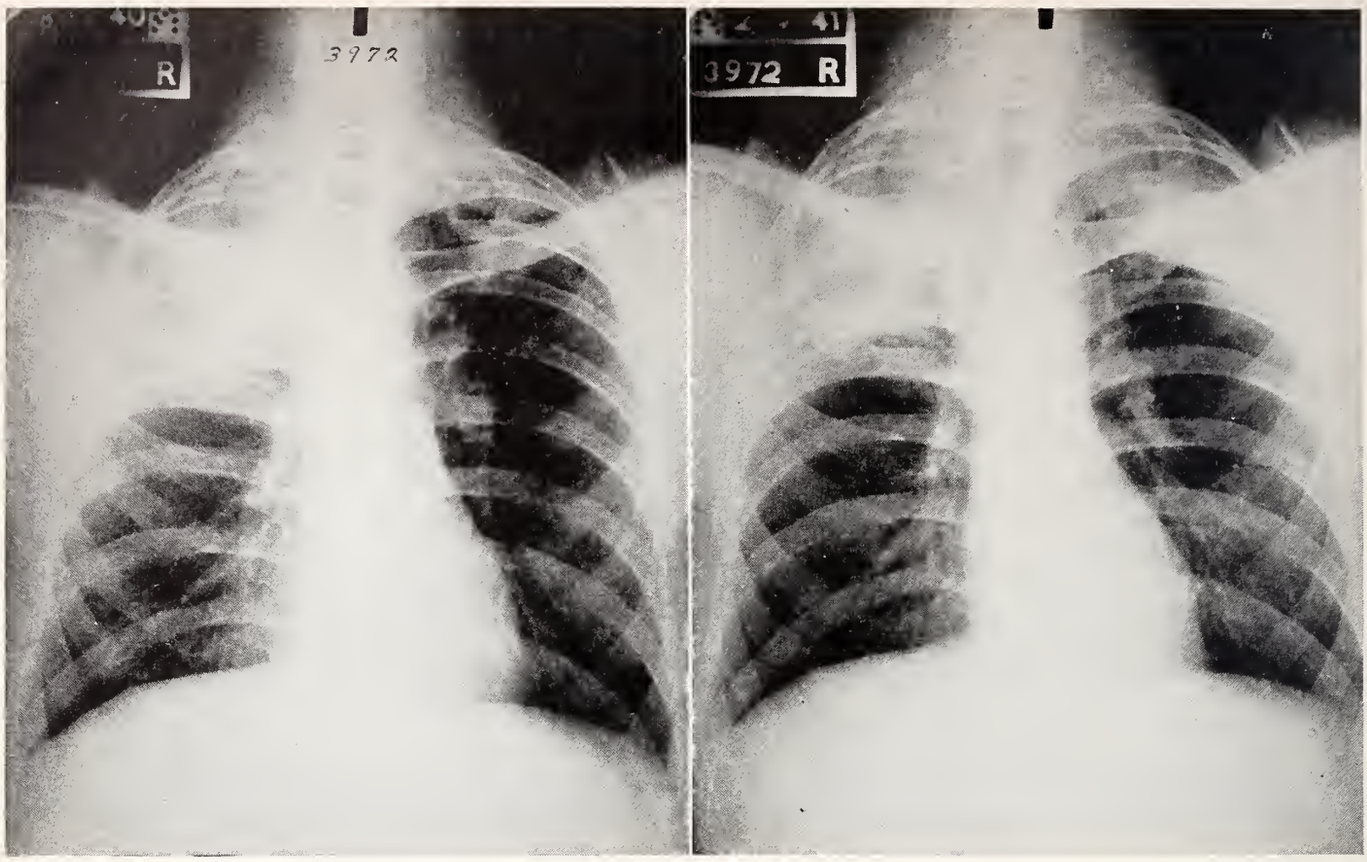

Fig. 1. Roentgenograms before and after bilateral extrapleural oleothorax. The cavity in the apex of the contralateral lung developed six months following the pneumonolysis done on the right side. Maximum functioning of uninvolved lung maintained on both sides.

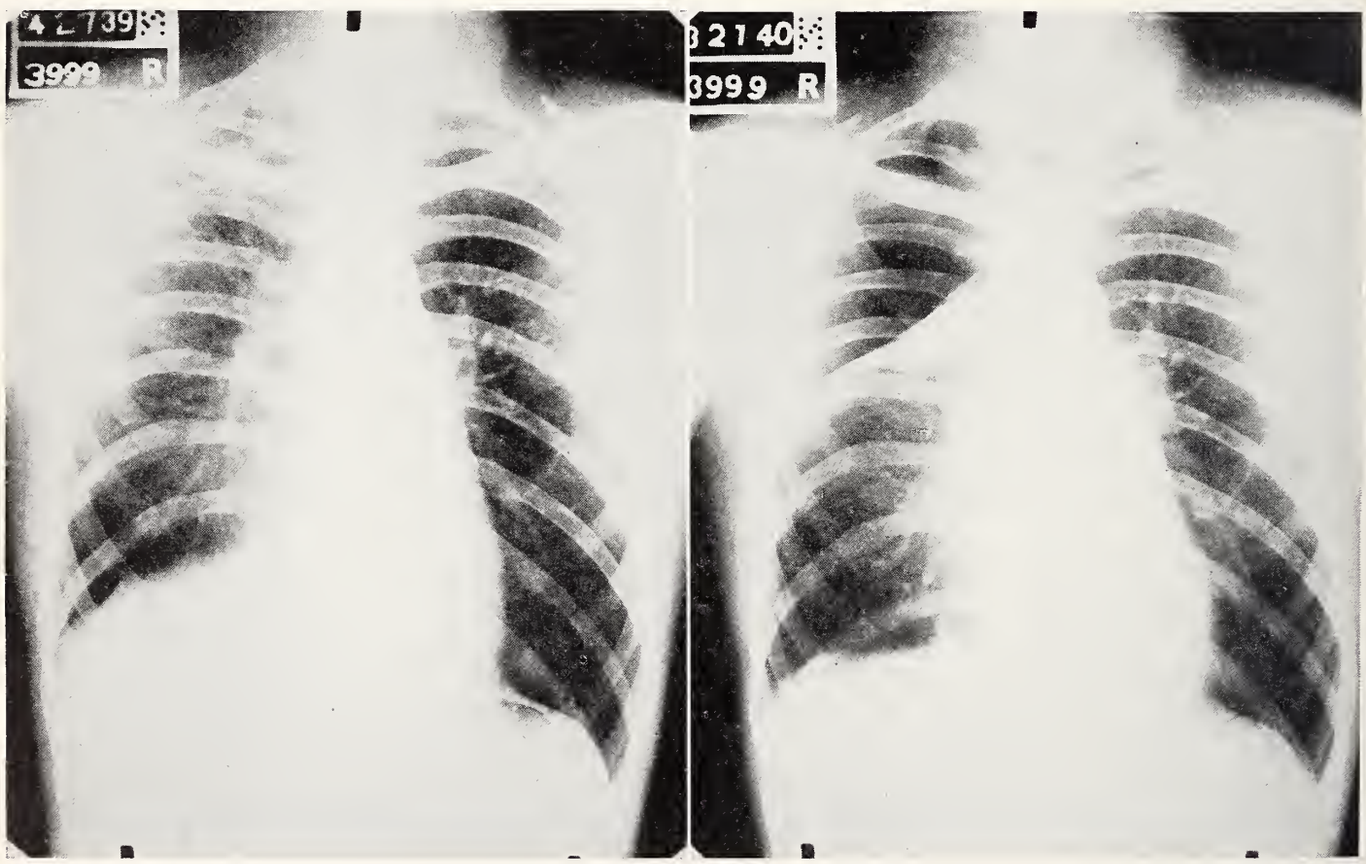

Fig. 2. Roentgenograms before and after the establishment of an extrapleural pneumothorax on the right side with a recent progressive lesion in the midportion of the left lung. Closure of cavity, conversion of sputum, as well as clearing of the contralateral lesion resulted.

oleothorax (Fig. 1) and the other had a secondary pneumonolysis in order to increase the size of her pneumothorax. This group also includes the two cases in which bronchopleural fistula occurred, one having a subsequent thoracoplasty with eventual satisfactory results. The other, now being treated by intercostal catheter drainage and classified as unimproved, is now being prepared for thoracoplasty.

Two of the series had progressive lesions in the contralateral lung at the time of operation. Of these, one died postoperatively of bronchopneumonia and in the other (Fig. 2) the result is satisfactory with subsequent improvement of the contralateral lesion. The remaining group of six had essentially negative contralateral lungs. In one the operated lung was involved with an advanced pneumonic infiltration throughout the upper lobe with cavitation. The remaining five, in whom all the results were satisfactory, might have been subjected to thoracoplasty. Three were young women with progressive lesions limited to the upper lobe which failed to stabilize on bed rest alone. Extrapleural pneumothorax was selected rather than thoracoplasty as the less radical of the two procedures. Extrapleural pneumothorax was chosen in the remaining two who had lesions with cavity involving only a small portion of the apex. Less good lung was sacrificed to control the pathology than would have been had thoracoplasty been the procedure used.

Table II is a list of the complications occurring in our group together with treatment and results.

While complications occurred following extrapleural pneumonolysis in nine patients they were of a serious nature in only five cases, causing death in two patients. The low grade empyema listed was easily controlled by oleothorax and did not affect the final results. Thirteen operations performed on the remaining eleven patients were attended by no complications.

Table III summarizes the results of the series as a whole.

TABLE II. EXTRAPLEURAL PNEUMOTHORAX

Cases	Complications	Treatment	Result
1	Empyema with contralateral spread	Irrigations	Dead
1	Postoperative pneumonia	Oxygen therapy	Dead
2	Bronchopleural fistula	1 Thoracoplasty 1 Intercostal drainage	Satisfactory Unimproved
1	Mediastinitis with loss of air space	Irrigations	Satisfactory
4	Empyema (low grade)	Oleothorax	Satisfactory

TABLE III. EXTRAPLEURAL PNEUMOTHORAX

	No. Patients
Satisfactory	16
Thoracoplasty required	1
Unimproved	2
Dead	2

The sixteen patients in the first group include one having a bilateral extrapleural pneumothorax and one having a subsequent lysis to increase the collapse of the original pneumothorax, making a total of eighteen operations. The case listed as unimproved is to be submitted to thoracoplasty in the near future in the hope of improving his status. The relatively high mortality is due to the application of this procedure to a group of patients including many who would be considered too poor a risk for thoracoplasty.

Discussion

While our series of cases is too small and our experience too short to warrant definite conclusions regarding the procedure of extrapleural pneumothorax, we have been impressed with the value of this procedure. In the hands of men trained in pneumothorax therapy, popularity of this procedure is bound to increase. Too much emphasis cannot be placed on the proper postoperative care of the collapsed lung. No other surgical procedure, with the exception of paraffin pack, can produce as efficient anatomical collapse of the disease with such a minimum loss of functioning lung, and it has its advantage over the paraffin pack in that the extent of collapse is not limited. The operation itself was withstood well by the patients and can be tolerated even by

those in whom toxemia is marked. The rapid collapse of the pathology resulting from the procedure seems to have no appreciable effect on the patient's condition. The reaction of the patient is not greater than that following an upper posterior stage thoracoplasty.

One of the most gratifying features of this procedure has been the rapid conversion of sputum. In fourteen of the eighteen surviving cases all specimens of sputum examined following establishment of pneumothorax have failed to reveal tubercle bacilli. These examinations have consisted of 24-hour specimens which had been concentrated in the usual way before being examined for the bacilli. Of the remaining four, one became negative two months following surgery; another, in which a bronchopleural fistula developed, remained positive until thoracoplasty was done seven months later. Of the remaining two, both operated upon within the past two months, one has cavitation in the contralateral lung, and in the other the cavity under the pneumothorax is still patent.

The complications following this procedure will be reduced, we are sure, with proper postoperative treatment. Empyema occurring is not usually as serious as in intrapleural pneumothorax and can be controlled by irrigation through the acute stage, followed by oleothorax. Bronchopleural fistula is the most serious complication of this procedure. While it has been felt that giant cavities with thin walls are very likely to necrose due to disturbance of circulation, the experience of Proctor and others has been that this does not generally occur.

When permanent collapse of the pathology is desired, it seems practical to us to convert the extrapleural space to an oleothorax. We have used this method for maintaining collapse in intrapleural pneumothorax where obliterative pleuritis has occurred and, after five years' experience, we have found no reason to discontinue it. We feel that extrapleural pneumothorax should be used not as a preliminary procedure to thoracoplasty but that this latter procedure is to be reserved only for the treatment of such complications as bronchopleural fistula and uncontrolled empyema. Extrapleural pneumothorax should not replace thoracoplasty. Except in a few cases we do not feel that our indications for thoracoplasty has changed but rather that the procedure of extrapleural pneumothorax widens the field of collapse therapy and provides us with an additional surgical procedure to be offered to a group of patients in whom formerly conservative treatment alone could be used.

We would like to group under the indications for extrapleural pneumothorax the following four groups:

1. Bilateral disease where preservation of the functioning lung is paramount. Where intrapleural pneumothorax has failed and the lesion to be collapsed is too extensive to use paraffin pack, extrapleural pneumothorax is the only procedure that can be safely offered to the patient.

2. Progressive lesions failing to stabilize sufficiently for thoracoplasty.

3. The "indolent" tuberculous lesion. Under this group, we mean to include those in which the extent has never become great, where cavity may or may not be present, but in which arrest of the lesion is not secured by bed rest with or without phreniclasis, and in whom intrapleural pneumothorax has been unsuccessful. These cases usually are young adults who have spent years in and out of the sanatorium. The lesions have never progressed to the stage where the patient or the doctor is willing to accept thoracoplasty as inevitable. In this group the reaction to surgery is minimal; the resulting extrapleural pneumothorax is very seldom accompanied by complications; and there is often a definite tendency of the collapsed lung to re-expand. We have noted this in a few of our cases over our short period of observation, and it has also been reported by Proctor, whose experience dates back to 1935. We feel that this group should be given the benefit of the possibility that their lung might re-expand after having been collapsed long enough to control the disease.

4. The progressive lesions of children. Included in this group are the lesions which begin as minimal and gradually spread, without cavitation or symptoms, in spite of the long trial of best rest. For several years we have felt that whenever possible this group should be treated by pneumothorax, as their eventual prognosis is not good. On the other hand, we have hesitated to consider thoracoplasty, particularly when cavitation and positive sputum are not present. As a result many of these patients have been kept on bed rest for long periods of time and have been eventually discharged only to be readmitted with further involvement of their lungs. We feel, for the same reason as given under the third group, that extrapleural pneumothorax is the procedure of choice. In addition to these reasons, the deformities such as scoliosis, so often seen when thoracoplasty is performed on the immature, are avoided.

Summary

A description of the procedure of extrapleural pneumonolysis for the production of extrapleural pneumothorax has been given together with an outline of proper aftercare. A presentation of our series of cases with a description of the complications encountered and the treatment of these has been given. A discussion of our impressions resulting from observation of this series particu-

larly stresses the efficiency of sputum conversion, the minimum of good lung sacrificed, and the importance of proper postoperative care. The use of oleothorax in maintaining permanent collapse rather than subsequent thoracoplasty has been advised.

THE RETINAL MANIFESTATIONS OF SUBACUTE BACTERIAL ENDOCARDITIS*

PAUL S. HAGEN, B.S., M.B.

Boston, Massachusetts

RETINAL hemorrhages of different types are commonly noted in subacute bacterial endocarditis. They appear and disappear at various intervals during the illness, often leaving little or no trace of their existence. Moore[6] states that hemorrhages occur at sometime during the course of the disease in almost all instances. Friedenwald and Rones[3] believe that the so-called "septic retinitis" first described by Roth[5] is rather characteristic of subacute bacterial endocarditis. Typically, this variety of retinitis consists of petechial hemorrhages with yellowish or white centers. Even more significance has recently been attached to these or similar lesions by Doherty and Trubek[1] who describe elliptical hemorrhages with white centers and state that they may be of aid in the early diagnosis of endocarditis.

Embolism of vessels of the retina and choroid is known to occur and is productive of various ophthalmoscopic pictures. Middleton and Burke[5] found embolism of the central artery of the retina but once in a series of eighty-eight cases.

Mention of involvement of the disk in subacute bacterial endocarditis has been omitted in the recent literature. Falconer, in 1910,[2] noted the occurrence of optic neuritis, but since his report, allusion to changes in the disk has been found but three times, *i.e.*, in the reports of Yater and Wagener, in 1929,[9] Friedenwald and Rones, in 1930,[3] and Middleton and Burke, in 1939.[5]

My interest in the disk lesions in subacute bacterial endocarditis was aroused by the observation of marked papilledema in a patient having normal spinal fluid pressure recently studied on the Medical service of the University of Minnesota Hospital. The present study was made in order to determine the incidence of disk involvement in subacute bacterial endocarditis and to determine the degree of correlation of these lesions with other manifestations of the disease.

Material

The case records of sixty-seven patients having subacute bacterial endocarditis were examined. All of these had been hospitalized since January, 1929. From this group thirty-seven cases were selected for study. These were chosen on the basis of a positive diagnosis together with a report of examination of the fundi. The diagnosis was confirmed by autopsy in seventeen instances. A record of positive blood culture was noted in all cases except one, but in this the diagnosis was confirmed at necropsy.

Results

The results of the investigation are given in the accompanying tables. Table I includes the results for Groups A and B, the cases with abnormal ophthalmoscopic findings. Group A includes those with disk involvement, Group B those with retinal changes alone. Group C, in TableII,* includes cases in which the fundi were normal.

Comment

The relatively high incidence of lesions involving the optic disk is noteworthy. Thirteen cases or 35 per cent of the series showed disk pathology.

Case number eight of Group A will not be included in the ensuing discussion since, in the

presence of a four plus Wassermann reaction, lues could not be excluded as the cause of the blurred disk margins.

Exact classification of the disk lesions is extremely difficult. Several possibilities present themselves: optic neuritis, papilledema, embolic neuroretinitis, or combinations of these. Troncoso[7] mentions intermediate forms between optic neuritis and papilledema that can be differentiated clinically only on the basis of the type of visual disturbance present.

There are several possible factors in the pathogenesis of these lesions. Toxemia, a mechanism which Falconer[2] favored, probably is of importance. Embolic processes in the retinal vessels should receive serious consideration. Nearly one-half of those cases with disk lesions showed evidence of emboli in the cerebral circulation either shortly before or after the report of the funduscopic examination. Since the retinal and cerebral circulations are so intimately related, it is easy to suppose that emboli would also lodge in the retinal vessels. This was found to be the essential pathology in Friedenwald's first case.[3]

Increased intracranial pressure as a cause of the edema of the nerve heads must be considered. In the present group the one reliable spinal fluid pressure reading was within normal limits, so the edema in at least one instance was not due to increased pressure.

Middleton and Burke's case number four developed cerebral hemorrhage from a mycotic aneurysm. The eye findings of an optic neuritis were present before symptoms of the hemorrhage occurred, but could have been the result of some leakage over a period of days.

Another factor known to cause abnormal funduscopic pictures is severe anemia.[1,4,7,9] Low hemoglobin values are noted in Groups A and B (with retinal pathology), but comparable reduction is also observed in Group C (without changes in the eyegrounds).

Reference to the tables will reveal that petechiæ are not always present in the cases showing disk lesions. No petechiæ could be found in case number four of Group A, although thorough searches evidently were made. However, it is of interest to note that in Group A, 91.6 per cent (eleven cases) exhibited external petechiæ, although they were recorded in but 55 per cent (eleven cases) of Group C.

Cerebral embolic phenomena occurred seven times in the entire series of thirty-seven cases. Six of these were among the group with nerve head pathology. Thus it is clear that disk pathology can be expected with considerable regularity in those cases of vegetative endocarditis showing evidence of cerebral emboli.

Variations in blood pressure, temperature, and leukocyte count failed to reveal significant correlation with the occurrence of nerve head lesions. Abnormally high blood pressures were not observed. The temperature elevation and leukocyte counts varied in approximately the same manner throughout the entire series. Most of the cases of Group A exhibited high leukocyte counts, but there are numerous counts just

TABLE I—GROUP B

as high among those of Group C. Urinalysis also demonstrated no outstanding abnormality characteristic of one group more than another.

Visual disturbance is, as one would expect, the one finding that seems definitely confined to the group with nerve head changes (Group A). The surprising fact is the relatively infrequent occurrence of visual disturbance in this group, although it is possible that there were some instances that were not recorded.

Falconer[2] believed that the finding of optic neuritis aids in making an early diagnosis of vegetative endocarditis. Therefore, it would be interesting to determine the amount of time which elapsed between the onset of symptoms of the disease and the appearance of the disk lesions. No conclusions bearing on this point can be drawn from the present study because the onset of the papilledema was exactly dated in but one case (number seven in Group A).

Summary and Conclusions

1. The subject of retinal findings in subacute bacterial endocarditis has been discussed and the literature has been reviewed briefly.

2. Thirty-seven cases of subacute bacterial endocarditis were selected for study on the basis of a positive diagnosis and a record of ophthalmoscopic examination.

3. Study of this series reveals that:
   a. Nerve head lesions are not infrequent, being present in 35 per cent of the cases.
   b. The nerve head lesions are correlated to some extent with visual disturbances and cerebral accidents. Blood pressure, temperature, hemoglobin, leukocyte count, and urinary study showed no correlation. Petechiæ are more consistently found in the cases with disk pathology.
   c. Marked bilateral papilledema may be present in vegetative endocarditis without elevation of the spinal fluid pressure.

4. More emphasis should be placed on ophthalmoscopic examination in subacute bacterial endocarditis, with particular attention paid on the condition of the nerve head. Eyeground abnormalities may prove of aid in diagnosis.

The writer gratefully acknowledges the advice of Dr. C. J. Watson in preparation of this manuscript.

TREATMENT AND END RESULTS IN APPENDICITIS*

ROLAND F. MUELLER, M.D., F.A.C.S.
Two Harbors, Minnesota

FOR several years there has been an intensive campaign intended to educate the public on the subject of appendicitis. This education encompasses two chief objectives: (1) admonition against the use of cathartics in the presence of abdominal pain and (2) advice to seek medical counsel early when abdominal pain is present.

The motive is to prevent complications of acute appendicitis from developing since it is conceded that the chief mortality is in the complicated cases. However, there is another phase to the reduction of appendicitis mortality and that rests squarely on our shoulders as physicians. This is to reduce the mortality of complicated appendicitis by improved treatment. This will create an immediate marked decrease in appendicitis deaths. Bowers,[2,3,4] in Philadelphia, is doing remarkable work in reducing appendicitis deaths in that city and the same measures can be undertaken everywhere by organized groups such as state or county medical societies.

Teachings of Wilkie and the recent work of Wangensteen[16,17] regarding the etiology of appendicitis leaves little doubt as to the cause being obstructive in the majority of cases. This obstruction may be caused by various factors: kinks, bands, retrocecal fixation, strictures or lymphoid tissue swelling; and with a normal luminal resistance to outflow, appendicitis may ultimately be produced.

Classification

A classification is used that is based on the gross pathology seen at the time of operation. This is most useful in interpreting end results from various methods of surgical treatment (Table I).

In the first group are included interval appendicitis, mildly acute, subsiding and chronic appendicitis. Obviously, each differs in the clinical picture but they are similar in methods of treatment and mortality.

The second group is that of acute appendicitis and consists of all cases in which the appendix is acutely inflamed or obstructed, in which perforation has not occurred and the peritoneum is not seriously involved.

TABLE I. CLASSIFICATION OF CASES
(At Operation)

	Average of Collected Cases from Literature (Percentage)	Author's Series (Percentage)
Interval, Chronic, Subsiding and Subacute Appendicitis	20 to 25	16.6
Acute Appendicitis	50 to 60	65
Acute Appendicitis: Ruptured with Early Peritonitis, Localized Peritonitis or Appendiceal Abscess	15	13
Acute Appendicitis: Ruptured, with Diffuse or Generalized Peritonitis	5 to 8	5.4

In a third group are placed cases of acute appendicitis, usually ruptured, with localized peritonitis or appendiceal abscess. The factor of time is not considered as of value in classification but rather the extent of the lesion.

In the fourth group are placed the peritonitis cases of unlocalized extent. The term diffuse peritonitis is preferred to all other terms as being the truest one to represent this condition rather than spreading or generalized peritonitis. It has been demonstrated that true generalized peritonitis occurs rarely.

Mild and Chronic Appendicitis

In the indications for operation, it is believed that appendectomy is justified in the interval following an acute attack. Conservatism is desirable in performing interval operations when the patient has not been personally seen in an acute attack.

Some believe that a diagnosis of chronic appendicitis is not warranted; others believe it

*From the Two Harbors Hospital. Read before the annual meeting of the Northern Minnesota Medical Association, Duluth, Minnesota, July 19, 1940.

quite common and operate accordingly. The majority believe that it does occur, that it is not common and that a most careful exclusion diagnosis is necessary before operation is justified.

Shelley[15] reports the follow-up of 704 patients operated on for chronic appendicitis. The highest percentage of cure in this group was obtained in patients with evidence of inflammatory change or obstruction found at operation. Patients with findings of tenderness in the right lower quadrant and muscle spasm and not showing evidence of acute inflammation pathologically obtained as much relief from operation as those showing acute inflammation. Many of those were doubtless cases of appendical colic so recently elaborated by Cherney.[5]

Rea and Kleinsasser[14] in a follow-up study of 143 cases operated with a diagnosis of "inactive appendix" point out the interesting fact that many patients recover from appendical colic who show no pathologic changes in the appendix.

Acute Appendicitis

There may be considerable difference of opinion regarding the frequency or indications for chronic or interval appendectomies, but there is practically universal agreement that in uncomplicated acute appendicitis, immediate operation is indicated. The manner of removal is not nearly so important as the necessity for removal. There is wide variation in the severity of the pathologic picture in this group from the mild to the gangrenous.

The surgical approach in appendectomy has many variations and all methods have their exponents. McBurney's incision or some modification is the most commonly used incision and many surgeons use it routinely. The appendix occasionally is found in an unexpected situation in which the McBurney incision increases the technical difficulties. In the majority of cases, the clinical examination will determine approximately the best method of approach to the appendix and will also give a clue as to the possibility of an abnormally situated organ. Consequently, a routine incision is not always desirable but it must be tailored to the case.

The paramedian incision over the right rectus muscle retracting the muscle laterally in its sheath fulfills every requirement for a satisfactory appendectomy. Extension of the incision is easily accomplished and other organs examined or treated surgically as necessary. The Battle incision or some modification is used by many surgeons.

The surgical technic will not be discussed except to emphasize adequate and complete hemostasis, use of fine catgut, use of suction rather than gauze to remove exudate or blood, protection of the abdominal wound from infected peritoneal contents and avoidance of gauze intraperitoneally. The stump is treated with phenol and alcohol though no harm has been observed by omitting this step. The stump of the appendix is inverted. The practice of inverting the stump is one that has been used by a number of surgeons for many years. It appears to be a more surgically clean method than leaving the ligated stump free or buried in the meso-appendix or omentum. Certain requisites are necessary for inversion: control of all bleeding, avoiding the puncture of vessels in placing the purse string suture and a cecal wall not seriously involved in the inflammatory process.

On the basis of experimental studies, Donaldson[6] concluded that inverting the stump was preferable and Kross[11] concluded that inversion resulted in complications, so experimental evidence does not seem to be uniform.

If drainage is indicated, and it rarely is, a Penrose drain is used. The wound is closed with fine chromic catgut interrupted sutures. Tension sutures are not used inasmuch as they never assume tension but merely approximate the subcutaneous tissues and these can be approximated more efficiently by direct suture with fine interrupted plain catgut sutures. The dressing is seldom changed until time for the removal of the skin sutures or clips unless wound inspection is desired or drainage has been used.

Treatment of Localized Peritonitis

The treatment of complicated acute appendicitis with peritonitis requires for success the full measure of knowledge, skill and judgment of the surgeon.

While immediate operation is indicated in uncomplicated acute appendicitis, it is not always so highly recommended when perforation or signs of peritonitis are present. Usually these patients have been sick a longer period of time or at least the lesion is more extensive. Their condition is not always ideal for immediate operation and corrective measures can be instituted

before operation that will in a short period of time better enable them to withstand surgical intervention and the immediate postoperative stage. The toxicity can be corrected by fluids, intravenously or subcutaneously, transfusion, if necessary, rest and relief of pain. Also, the diagnosis is not always entirely obvious at the time of admission and observation is advisable to obtain more information before making a decision, during which time these measures can be carried out. Operation is preferred in all cases of this class or thought to be in this class after the dehydration has been corrected and any other toxic symptoms relieved. This practice of operation after correcting toxicity is early operation as contrasted with immediate operation.

Appendical abscess is treated in the same manner. An abscess is merely a stage of localized peritonitis and, consequently, deserves treatment on the basis of pathology rather than size or duration of the lesion. When the abscess surrounds the appendix and is small and mobile, it may be removed in its entirety; otherwise, the effort is made to open into the abscess and protect the uninvolved peritoneum. The appendix is removed in all cases of perforation and of localized peritonitis, if possible. In the occasional case, removing the appendix may entail the separation of barriers best judged to be left undisturbed. The appendix was removed in all cases reported in this series.

Drainage is usually but not always practiced with localized peritonitis. Well walled-off perforations with a small amount or possibly no pus present do not always require drainage even with some inflammatory reaction in the surrounding tissues. In the presence of frank pus, localized or unlocalized, drainage is usually indicated. When draining, a Penrose drain gives satisfactory results, one usually being sufficient to insure a sinus formation.

In the postoperative management, these cases are treated similarly to those of diffuse peritonitis.

Treatment of Diffuse Peritonitis Complicating Acute Appendicitis

There has been great controversy in the method of treatment of this truly serious surgical disease. The deferred method or Ochsner treatment of appendicitis with peritonitis has many advocates[1,8,12] who cite very good results with this method. Equally good results are reported by other surgeons[9,10,13] using early operation as the method of choice. The chief principle in the deferred method is absolute rest of the gastrointestinal tract. This consists in the use of continuous gastroduodenal suction, relief from pain, a balanced intake of water, minerals, intravenous dextrose and blood, and bed rest. Abscess formation is treated by surgical drainage if the abscesses do not resolve spontaneously. After the symptoms and signs have subsided and the patient recovers, the appendix is removed by interval appendectomy two to four months later.

The objection to unqualified use of the deferred treatment in peritonitis is that this treatment is best reserved for only a small percentage of cases and it is not always easy to say which cases fall into this group. Each case must be individualized. There is no assurance that a hospital bed, ice bag, morphine and fluids will necessarily result in subsidence of a peritoneal infection. Also, it is difficult to say just when peritonitis is present, and, if present, whether it is spreading or stationary. It is the contention of Ochsner that spreading peritonitis is definitely harmed by operative trauma. Ochsner admits that conservative treatment is very difficult and taxes the surgical judgment to the utmost and also states that the inexperienced surgeon will do better to operate on these patients than to institute conservative or deferred treatment. It may be pointed out, however, that a fundamental principle in the treatment of a diffuse peritonitis may be the removal of the source of infection. In some cases of diffuse peritonitis there is a continuous leakage taking place from the perforated appendix. Furthermore, the occurrence of localization in any one case is not certain. Even if localization occurs, it may break down into a diffuse peritonitis.

Immediate operation is to be condemned because it carries a high mortality. These patients are in poor general condition because the lesion is extensive, they are dehydrated by vomiting, and they are weak because of lack of rest caused by the pain. With operation superimposed upon this poor general condition, a high mortality results. As opposed to deferred treatment or immediate operation is treatment by early operation. Again the definition of early operation is operation after the general condition of the patient has been improved to the maximum by cor-

rection of toxicity, dehydration and exhaustion. Obviously, no definite rules can be laid down as to when the patient is in the best condition. The judgment of the surgeon must be the final deciding factor rather than any one laboratory procedure or any sequence of symptoms. "The extent the lesion has affected the individual is more important than the extent of the lesion." (Elman[7])

In the usual patient admitted with diffuse peritonitis, absolute rest is insisted upon in so far as compatible with treatment. Intravenous saline and dextrose solutions are given and blood if indicated. Gastroduodenal suction is started and morphine is given for the relief of pain if the diagnosis is unquestioned. Within a few hours, improvement is usually noted, and the patient is then operated upon with a better chance of recovery. The surgical approach is carefully determined on the basis of examination and the probable location of the appendix. Operation itself is carried out rapidly but not at the expense of gentleness or omission of necessary steps. Suction is used to remove all peritoneal exudate or pus. The wound must be protected against contamination from the infected peritoneal contents. The appendix should be removed and unless perforation is recent, drainage is instituted with one or more Penrose drains along the lumbar gutter and in the pelvis. The wound is either closed about the drain or up to and including the fascia of the external oblique muscle or the anterior rectus fascia and the subcutaneous tissues and skin are left open and secondary closure carried out later.

Good and adequate postoperative treatment is needed by these acutely ill patients. Gastroduodenal decompression is routinely practiced until audible peristalsis is heard. Five per cent dextrose with saline and alternately without saline is given slowly in adequate daily amounts as judged necessary by the urinary output. The relief of pain, of course, is continued with morphine in necessary dosage and frequency. Chemotherapy is used in most cases, depending upon the severity of the infection. Bacteriological findings of the material obtained at operation is seldom useful as a guide in the treatment.

Sulfanilamide has been used with increasing frequency in these cases, being administered intravenously immediately before or after operation and intramuscularly or subcutaneously with saline or other infusions thereafter. Ravdin[13] reports the use of sulfanilamide in 257 cases of acute appendicitis complicated by peritonitis with only one death. This is the lowest mortality appearing in the literature for a series of cases of this length and severity. He used an average of 8 Gm. the first day and reduced the dose each day thereafter depending upon observation. Transfusions were used somewhat oftener in his series of sulfanilamide treated cases. In the postoperative management, transfusions are frequently desirable even though indications are not imperative. While routine use of transfusion is not recommended, most of these patients will require one or more to supply protein if for no other reason. Children particularly seem to derive much benefit from transfusions, possibly because they require a proportionately greater amount of protein than adults. Gatch[9] has particularly emphasized the use of transfusions in these serious complicated cases in children and attributes his low mortality of .6 per cent to the more frequent use of transfusions.

It is believed from results obtained in the series of cases reported that early operation is a method of choice except in the rare case where an overwhelming infection is obviously present. However, the virulence of the infecting organism or organisms is a factor influencing the course of events.

There is one type of case that demands particular consideration. Patients who on admission present a high temperature of 104 to 106, a rapid pulse and signs of advanced systemic infection represent a virulent invading type of infection. A history of chills at the onset of the illness may be given but this does not necessarily indicate a virulent infection. These patients are restless and may be mildly irrational at times. The symptoms and signs of systemic infection dominate the picture. The abdominal symptoms may not be outstanding but signs of peritonitis are present. The infection will not be helped by immediate operation. Moreover, the patient will be less able to combat the infection in the lymphatics and blood stream after such an operation.

A routine peritonitis régime of treatment is instituted consisting of gastroduodenal decompression, fluids parenterally, relief of pain, and, in addition, measures to combat the infection must be instituted with emphasis on absolute rest, adequate chemotherapy and transfusions.

After recovery, appendectomy is done any time after three weeks. There may be recurrence. Consequently, too long a waiting period is not advisable. Roughly, one per cent of all appendicitis cases fall into this group which present, on admission, peritonitis with serious systemic invasion. These patients are always treated conservatively. If there is some doubt as to the patient being in this class, operation is carried out in preference to deferred treatment.

In the postoperative treatment of diffuse peritonitis, the watch for complications must be vigilant, and, when present, they should be recognized early and dealt with wisely. Administration of oxygen by nasal catheter or oxygen tent reduces the respiratory effort when abdominal distention is great and benefits the patient to a great extent. It is frequently desirable to administer vitamins, particularly when nourishment is not taken for a period of several days since the supply in the body tissues becomes rapidly depleted under such circumstances.

The most common complications are wound infection, and, second, abscess formation. Treatment of wound infection scarcely needs amplification. Adequate drainage is indicated, but this does not mean laying the entire wound open. Drainage and counter-drainage will suffice and the time of complete healing will thereby be shortened. Wound infection involving all layers will often result in postoperative hernia unless the patient is confined in bed for longer than the usual period (Table II).

Peritoneal abscess formation is usually indicated by persistence or secondary rise in the temperature curve but usually has been recognized previously or suspected when daily examination is made. An abscess near or about the appendix will often drain into the sinus provided by the drain. Subphrenic abscess, fortunately, is not a common complication, but must be considered when the presence of a hidden suppuration is suspected. Early drainage is necessary, depending upon the space involved.

TABLE II. COMPLICATIONS OF APPENDECTOMY

TYPE	Averages from Literature (Percentage)	Author's Series (Percentage)
Pneumonia	6	3
Wound Infection	5	6
Pulmonary Atelectasis	4	5
Intraperitoneal Abscesses	3.5	1
Fecal Fistula	1	1
Thrombophlebitis	1	0
Peritonitis	1	0
Subphrenic Abscess	.5	0
Pleurisy	.5	1
Liver Infection	.5	0
Embolism	.2	0

Appendicitis in Children

Acute appendicitis in children is the same disease and should be similarly treated. Generally it is stated that perforation occurs early in children. This may partly be due to the fact that the onset of the disease is recognized later in children. The loss of protein in the peritoneal exudate often results in protein deficiency in children. Consequently, they need transfusions oftener than adults.

Serum Therapy

From the European continent have come sporadic reports relative to the use of serum in connection with surgical treatment of appendicitis. This is in the nature of an antitoxin and is administered intraperitoneally as well as intravenously and intramuscularly. The reports to date have not been sufficiently comprehensive to establish this method as valuable in the treatment.

Mortality in Appendicitis

A survey of mortality in appendicitis published in the past two years gives us an average mortality rate of all types of cases of about 2.6 per cent. In collected series, the average mortality ranges from 0.4 to 5 per cent.

For different types of appendicitis, the rates vary. In chronic or interval appendicitis, there is practically no mortality. In acute uncomplicated appendicitis, the average mortality is 0.5 to 0.8 per cent. For acute appendicitis with localized peritonitis, mortality varied in different reports from 0.4 to 8 per cent. For diffuse peritonitis, the mortality in this series varied from 0.4 to 37 per cent.

The author reviewed a series of 114 consecutive cases of appendicitis treated at the Two Har-

bors Hospital within the past two years, 107 of which were personal cases. Among these, eighteen were for interval, chronic, subsiding or subacute appendicitis, seventy for acute uncomplicated appendicitis, fourteen for acute perforated appendicitis with localized peritonitis, and six complicated by diffuse peritonitis. In six instances appendicitis was diagnosed but no operation was performed because of the mildness of the attack or the patient's wish to defer operation. There were no deaths (Table III).

TABLE III

	Number of Cases	Average Age	Average Number of Previous Attacks	Complications Percentage	Mortality
Interval or Chronic Appendicitis	18	24	1.8	5.5	0
Acute Appendicitis	70	26	1	13	0
Perforated Appendicitis (Localized)	14	24	.6	36	0
Perforated Appendicitis with Diffuse Peritonitis	6	24	2	50	0
Appendicitis No Operation	6	36	.15		0

Conclusions

Indications for appendectomy in nonacute cases are broadened to include mild acute or so-called subacute appendicitis, appendical colic or appendiclausis, and cases seen in acute attack but not operated during the acute phase. Interval appendectomy is suggested as one means to decrease appendicitis mortality since cases of severe appendicitis with peritonitis usually give a history of definite previous attacks.

It is necessary to correct toxicity in most cases to obtain the lowest mortality in appendicitis complicated by localized or diffuse peritonitis.

In the treatment of these severe cases of appendicitis, the pre-operative treatment, the time of operation and the postoperative management are paramount to technic or type of operative procedure.

Early operation after adequate pre-operative treatment is recommended for all types of complicated appendicitis in preference to deferred operation except for the occasional case which presents the picture of a virulent invading systemic infection. Deferred treatment followed by appendectomy is recommended for the 1 to 2 per cent of cases comprising this group.

APPENDECTOMIES*

C. G. OCHSNER, M.D., F.A.C.S.
Wabasha, Minnesota

FOR the past few years I have been watching with interest some of the statistics on appendicitis. I have been surprised at the high death rates and I have noted that surgeons reporting from their own private practices have, on the whole, had lower mortality rates. That is, of course, entirely logical. At the same time, I have developed a few ideas, in no way new or original, the routine adoption of which have given us such good results that I feel it may be of interest to discuss them here and pass them on into literature to help swell the already overflowing volumes on this subject.

In the past fifteen years little or nothing has been added to help the physician solve the problem of diagnosis on appendicitis. During this period we have, however, obtained tremendous help in its treatment. We have learned to standardize treatment technic and in a small way this has helped to reduce our deaths. There is another factor to which we should give much credit and that is the improvement in the material we work with, such as our anesthesia, antiseptics, autoclaves, instruments, suture material, and especially the advancement and standardization of hospital sterilization technic.

It is not my object to attempt to emphasize or add anything to the diagnostic problem in appendicitis. There is one observation that I should like to record. It is my firm belief that the first man to examine a case of acute appendicitis is the man in the best position to make the diagnosis. The first, light, careful examination of the abdomen reveals the most information. I have always felt that a gas-filled, palpable cecum is one of the very important findings and as soon as one begins deep palpating over the cecal area this gas will pass off and many times, especially in retro-cecal appendices, the patient will immediately complain of less tenderness. I believe this finding, especially in the absence of an otherwise inconclusive picture, is a great help in arriving at an early diagnosis.

We wish to report today on a series of 219 consecutive appendectomies performed at St. Elizabeth's Hospital. Of these, 198 were done for acute or sub-acute appendicitis and were accompanied by no mortality. In twenty-one cases the appendix had grossly ruptured and peritonitis was established to either a very limited or an extremely generalized degree. There was one death or a 4.7 per cent mortality. This death was that of a fifteen-month-old infant who was moribund upon admission and an exploratory operation was advised since the history given by a very ignorant mother suggested an intra-abdominal accident and a peritoneal irritation other than appendiceal in origin.

It is true that this series of cases is small and a little hard luck can make the difference between a low or a high mortality rate. However, I feel it is large enough to permit some inferences.

The economic level of patients and the intelligence and general state of education of a community are important factors. I believe that here in Wabasha County the average patient is well informed, more so than in the average community or certain sections of the larger cities. There are relatively few who do not appreciate the seriousness of a persistant stomach ache and only the very ignorant will resort to laxatives. All these facts are important since it means that we see our appendicitis patients early. The public is more and more beginning to realize that an appendectomy done early in the course of disease is a simple thing with practically no risk. With modern sedatives and anesthesia it is a nice vacation and not a period of suffering.

As to the treatment, there is nearly as great a variety of opinions as there are surgeons operating, and mortality rates vary tremendously. For one thing, I feel that spinal anesthesia on those cases where it can be employed (and in appendicitis it can almost always be used) is by far the finest anesthesia for abdominal surgery. Our patients usually receive 2 capsules of seconal or nembutal one-half to three-fourths of an hour before operation and by perfecting the technic of spinal puncture we have been able to instill

*Read before the Wabasha County Medical Society, Plainview, Minnesota, October 10, 1940.

our anesthesia without the patient, generally in deep sedation, being fully aware of what is going on. With the coöperation of the anesthetist by engaging the patient in an interesting conversation much can be done to relieve the patient's apprehension. The result is that most patients will later confess that during the operation itself they actually had a good time. Post-operatively, in our experience, the spinal patients are much more comfortable and complications are less.

As to the technic of the operation itself, I firmly believe the McBurney incision should be universally adopted. The only exception would be the interval appendix with pelvic or gall-bladder and stomach pathology. Occasionally, one sees a very definitely localized appendicitis outside the right lower quadrant. These cases are probably best approached with a short incision directly down over the maximum point of tenderness. In the case of the very acute or perforated appendix, I believe one should always approach these through a short McBurney's incision.

One commonly hears that through a McBurney's incision it is more difficult to handle bound down, retrocecal appendices. To my way of thinking, that is exactly where McBurney's incision serves its greatest purpose, because in dealing with any retrocecal appendix the simplest procedure is to roll the cecum medially and use an entirely lateral type of approach. On these cases, therefore, the more lateral the incision is the easier is the operation and I have repeatedly found this to be true in all forms of retrocecal appendices and even in retroperitoneal types. In removing the appendix I believe the simpler a technique one employs the better. We are now simply, with one full loop, ligating the entire meso-appendix with one tie; then ligating and cauterizing the stump. I have given up the purse string suture entirely and I believe it is only a possible source of trouble.

Moreover, with the relaxation secured from spinal anesthesia, we have always been able to explore the pelvis and with relatively little difficulty operate on the right side of the pelvis. On the whole, however, when handling a very acute appendix the less exploring and the less additional operating, the better.

In the twenty-one cases of ruptured appendicitis in this series we have employed a technic that, although it is not very new, nor is it original with me, I believe is life saving. In all cases where we encounter a perforated appendix and it is possible to remove the appendix we insert a large catheter into the old appendix stump directly into the cecum and with silk ligate the stump about the catheter. The catheter is then brought out through a stab wound laterally and below the incision. The wound is left quite open. Penrose drains are inserted down to the old appendix bed and the wound is loosely packed open with iodoform gauze. Postoperatively, the catheter is allowed to drain into a bottle and a half-ounce of normal saline is injected into the catheter every two hours to keep the tube patent. We have not had to resort to nasal suction in these cases with one exception. This patient developed a postoperative obstruction proximal to the cecostomy and had to be re-operated upon. The postoperative course of these cases is remarkably smooth and has to be observed to be appreciated. The abdomen is always flat, the patient is allowed to drink water soon after the operation, and has no gas pains and no abdominal distention. In twenty-four hours the iodoform gauze is removed and in three days all drains are removed. In seven days the adhesive tape fixing the catheter to the side is removed and the catheter is allowed to loosen on its own accord. Generally by the following day (eighth) it can be removed. I have often been asked about a resultant fecal fistula. The stab wound through which the catheter is brought to the outside is of course just large enough for the purpose and in every case within 24 hours after removal of the catheter this opening is closed and we see no more fecal drainage. Theoretically, one should be able to accomplish the same end result with continuous suction, especially by the use of a Miller Abbott type tube, but the insertion of this catheter is such a simple thing, its action is so positive and the patient is so much more comfortable, that I cannot understand why it is not more universally adopted. The advantages of bowel decompression, particularly in the area of greatest involvment, can easily be understood. A decompression in this area will decompress the entire intestine and that, too, has been clinically proven. Even toxicity is somewhat lessened with facilitation of elimination and decompression.

Because of the advantages of doing an appendecostomy, or a cecostomy, whichever one pre-

fers to call it, I think one should make it a point to remove every appendix in operating on a ruptured appendix. The only exceptions we have allowed ourselves are those cases where, in a well walled-off abscess, the appendix and the meso-appendix form a part of the abscess wall. In those instances the removal of an appendix is bad surgery and defeats every effort of nature. I believe these abscesses should be well drained.

The controversy still exists as to when to operate on a ruptured appendix. Dr. A. J. Ochsner himself soon realized, after he published his paper describing his method of treatment of appendicitis, that there could be no generalities made. It is simply foolish to attempt to "splint the bowels" in a case that has been thoroughly agitated with large doses of laxatives. Also there are the cases one sees where instead of the usual constipation, the patient presents a history of marked diarrhea. I believe the sooner one operates upon these people with removal of the appendix followed by an appendecostomy, the better. On the other hand, there are the patients showing a severe toxic picture, high fever, a definite spreading peritonitis with either the early, board-like or the later, distended abdomen. These patients certainly should be treated conservatively until localization has occurred. It is not always possible to absolutely establish clinically the certainty of perforation. I believe where any doubt exists, operation should be performed regardless of the length of time the attack has existed. Occasionally, after a few hours' rest with morphine and intravenous fluids, an abdomen that at first appeared typically like an early peritonitis will show a localization entirely in the right lower quadrant and operation done immediately will save the patient the risk of a peritonitis.

I have not attempted to elaborate on statistics in this series. It is sufficient to say that in 198 successive appendectomies the appendix was removed because of disease without a fatality. This series excludes those cases in which routine appendectomies were done along with some other operation.

In the twenty-one cases of perforated appendicitis, there were sixteen instances of generalized peritonitis and five in which the peritonitis was localized. In twelve of those cases ether was used and in nine spinal anesthesia. In thirteen cases an appendecostomy was done and in five the abdomen was closed without drainage. In one case the abdomen was drained without an appendecostomy and in two cases the appendix was not removed. One of the two cases happened to be a little girl in very critical condition with a severe pneumonia.

Of the twenty-one patients with perforation there were four who developed complications. One patient, a fifteen-month-old infant, died of toxemia within eight hours after operation, the only death in this entire series. One patient developed a postoperative obstruction and had to be re-opened. We almost lost this patient. Another patient developed a fecal fistula from the drain wound and was in the hospital three and one-half weeks. One patient developed a hemorrhage from a previously diagnosed duodenal ulcer.

Summary

1. One hundred and ninety-eight successive appendectomies for acute and interval appendicitis were performed without any mortality.

2. Twenty-one cases of perforated appendicitis with peritonitis are reported with one death, a 4.7 per cent mortality.

3. The routine use of an appendecostomy or cecostomy is strongly urged in all cases of perforated appendicitis.

"The medical profession now represents the only important group in the United States which, while harassed from within and without, has shown no slightest signs of capitulation or even of retreat.

"On the basis of this fact, it has automatically placed itself in the position of an intellectual leadership of those individuals, groups and institutions which seek to preserve the important elements of individual freedom and initiative and the principle of 'Free Enterprise.'

"If we live up to this opportunity and the serious responsibility it entails, the physicians of this country can—while preserving the independence of American Medicine—most importantly and vitally serve their country during its period of crisis and greatest stress." —Dr. Edward H. Cary, President National Physician's Committee for Extension of Medical Science.

CASE REPORTS

CLINICAL-PATHOLOGICAL CONFERENCE

Presentation of a Case

MINNEAPOLIS GENERAL HOSPITAL

Frank C. Andrus, Pathologist

History.—The case is that of a fourteen-year-old female child who was first seen in August, 1937, because of the development of enuresis. A low fluid intake and the administration of sodium chloride were advised. In June, 1940, laboratory examination revealed her hemoglobin to be 48 per cent with an erythrocyte count of 2,620,000 and a normal leukocyte count. Urinalysis showed a trace of albumin, an occasional red cell, 25 to 30 pus cells per high power field and a specific gravity of 1.011.

She was admitted to the hospital on December 29, 1940. The mother stated that the child had been quite well until approximately one year previously when she started to complain of marked weakness and anorexia. It was also noted that she drank excessive amounts of water and urinated rather frequently. On December 21, she had her first menstrual period and bled excessively. Several days prior to admission she developed marked frequency of urination, voiding every ten to fifteen minutes but passing only small amounts of urine. She complained of severe thirst and difficulty in breathing. On December 28, marked puffiness was apparent about the cheeks and eyelids. Past history was negative save for scarlet fever in 1938 and pneumonia in the winter of 1939. There had been frequent nose bleeds during the fall of 1940.

Physical examination revealed an under-developed and markedly anemic child who appeared to be acutely ill. Her respirations were Kussmaul in type and the child was in a semi-stuporous condition. She was restless and there was a tremor of her lips and hands and an increased muscle tone, bordering on rigidity. The Chvostek and Trousseau signs were negative. Dry blood was noted in the nares. The mucous membranes were very pale and dry. The lungs were negative to physical examination. A short systolic murmur was heard over the precordium. The heart rate was rapid and the blood pressure was 145/90. The liver edge was palpable two finger-breadths below the right costal margin. No other masses were felt. There was puffiness about the face but no edema of the extremities.

The blood urea nitrogen was 166.6 mg. per cent and the creatinine was 3.1 mg. per cent. The carbon dioxide combining power was 7 volumes per cent. The blood phosphorous was 8.2 mg. and the blood calcium was 7.5 mg. per cent. The plasma proteins were normal.

The patient was given 500 c.c. of sodium bicarbonate solution intraveneously and on the following day, the carbon dioxide combining power had risen to 27 volumes per cent. A flat plate of the abdomen was negative. X-rays of the long bones revealed relative decalcification. An electrocardiographic tracing was normal. Urinalysis revealed a trace of albumin, an occasional red blood cell, and a few pus cells. The hemoglobin was 44 per cent, the erythrocyte count 2,590,000, and the leukocyte count 8,300 of which 89 per cent were polymorphonuclears. The reticulocyte count was 4.1 per cent; the bleeding time 7 minutes and 17 seconds and the clotting time 6 minutes and 45 seconds; the platelet count was 210,000. Two blood cultures were negative. The patient was given a blood transfusion but her hemoglobin, instead of rising, remained at about the same level and during the last few weeks of her hospital stay, it gradually dropped so that at the time of death, her hemoglobin was only 30 per cent.

On the day following admission, her temperature rose to 103 degrees and thereafter was septic in type, varying between 96 and 103 degrees. The child's condition at no time permitted pyelographic studies. On January 9, 1941, the patient complained of pain on inspiration. Crepitant râles were heard in the right lower lung field and a pleurisy or an early pneumonia was suspected. The systolic murmur which had previously been heard was louder and somewhat harsher in character. On January 15 urinalysis revealed 60 to 80 pus cells per high power field with 6 to 8 red blood cells and, on January 19, 1941, a non-fluctuant swelling was noted in the region of the left parotid gland. Several days later, swelling appeared over the parotid region on the right side also. Pus exuded from the left external auditory canal. Subsequently, the right ear also drained pus. At no time during her hospital stay did her condition show any noteworthy improvement. She ran steadily downhill and expired on January 31, 1941.

Clinical Diagnoses: (1) Hypoplastic kidneys; (2) uremia; (3) bronchopneumonia.

Autopsy.—The body is that of a rather slightly developed and poorly nourished white girl measuring 138 cm. in length and weighing an estimated 68 pounds. There is bilateral swelling in the region of the parotid glands. A fluctuant abscess is present behind the left ear. Draining sinuses are present in the region of the lateral aspect of the left thigh, over the left hip laterally, and in the right inguinal region. A decubital ulcer is present over the sacrum.

The peritoneal cavity shows no abnormalities. The right pleural cavity contains approximately 1,000 c.c. of turbid fluid. At the base of the right lung, an encapsulated empyema pocket is found containing approximately 50 c.c. of thick, green pus. The left pleural cavity contains 600 c.c. of clear, serous fluid. The pericardial sac is normal.

The heart is normal save for a soft vegetation 8 mm. in diameter on the auricular surface of the mitral valve. Scattered throughout all lobes of the right lung, there are numerous abscesses varying in size from 2 mm. to 1.5 cm. in diameter. Patches of bronchopneumonia are also scattered throughout this lung. The left lung shows bronchopneumonia but no abscesses.

The spleen is negative. The liver appears somewhat fatty. The gastro-intestinal tract is normal throughout.

The right kidney weighs 40 grams and the left 70 grams. The capsules strip with moderate difficulty tearing with them small pieces of renal parenchyma. Both kidneys contain numerous cysts varying in size from several millimeters to three centimeters in diameter. Numerous cysts contain thick, greenish-yellow pus. Very little kidney substance remains. The urinary bladder and genital organs appear normal.

The parathyroid glands appear to be definitely enlarged. The abscess behind the left ear is found to communicate with the mastoid cells on that side and from there with the middle ear. Smears of this pus reveal gram positive cocci in clusters.

Anatomic Diagnoses: (1) Congenital polycystic kidneys; (2) pyelonephritis; (3) pyemia; (4) acute bacterial endocarditis; (5) pulmonary abscesses, right; (6) bilateral confluent bronchopneumonia; (7) Bezold's abscess, left; (8) parotitis, bilateral; (9) empyema, right.

Discussion

Dr. Milton M. Hurwitz: Congenital polycystic kidneys are seen once in every three to five thousand hospital admissions. One-third of individuals with polycystic kidneys are stillborn or die within the first month of life. If they survive this period, death rarely occurs before the age of twenty years. Most go on to death in the fourth or fifth decades. One explanation of the rarity of the symptoms under the age of twenty years is that in the young patient, the remaining islands of renal parenchyma undergo compensatory hypertrophy to carry out the work of that part of the parenchyma which has been destroyed, whereas, in older patients, this property of compensatory hypertrophy is lost. Approximately the same number of males as females are afflicted with the disease.

The clinical course may be gradual or acute, the chronic form being more common. Death may be due to renal insufficiency, this being the most common cause. If renal infection supervenes, the infection may cause death. These patients, because of their anemia and general debilitated condition, seem to be more prone to intercurrent infections. Hypertension is associated with this condition in more than half of the cases.

Pain is an outstanding symptom. It is located usually in the lumbar region or flank. It is usually dull and aching in character and quite constant. It is probably due to the pressure resulting from the enlargement of the cysts. If hemorrhage occurs into a cyst which communicates with the renal pelvis, renal colic may result due to the passage of blood clots down the ureter. General symptoms are due to uremia or infection. Half of the patients have anemia. An enlarged kidney is palpable in over 95 per cent of the cases; in 75 per cent of the cases, enlarged kidneys are felt bilaterally. Gross hematuria is an early symptom in one-third of the cases. This is intermittent in type. Retinal changes may be found in those who develop hypertension. The urine usually contains some albumin, leukocytes and erythrocytes. Erythrocytes are present microscopically in about 45 per cent of the cases.

The kidneys retain their shape regardless of whether they are small or large. In the great majority of cases, the kidneys are definitely enlarged. In one patient seen at the Mayo Clinic, kidneys weighing 17 pounds each were discovered. The contents of these cysts is usually watery in consistency. Occasionally, it is colloidal in character and if infection has supervened, pus is found within the cysts. The color of the fluid is usually light yellow but may be brown, red, or black, depending upon the amount of blood mixed with the contents of the cyst. Some of the cysts are found to communicate with the renal pelvis; others are isolated. Associated anomalies in the form of liver or pancreatic cysts are found fairly frequently. The number of functioning nephrons is markedly reduced, only occasional islands of parenchyma persisting.

The hereditary aspects of polycystic kidneys are well recognized. Cairns reported ten cases in forty-two members of a family over a period of three generations. Fuller found a family of twenty-seven members over a period of four generations that had nine members afflicted with this disease. Sprent found five syblings affected. The tendency appears to be a dominant one.

Medical treatment consists of diet, treatment of uremia, when it occurs, and urinary antiseptics when indicated. Surgical treatment consists of incision of the cysts to relieve pressure or to stop hemorrhage or nephrectomy. The latter is recommended by Walters and Braasch only when there are definite indications for this procedure, such as a massive infection with pyonephrosis, calculus, renal neoplasm, or tuberculosis. Such a procedure should never be done if the function of the remaining kidney is not found to be within normal limits.

Dr. Frank C. Andrus: This is an unusual type of hereditary or familial disease of the kidneys which points out a good deal in renal physiology. As the cysts increase in size, or as infection supervenes, we have the development of renal insufficiency or sepsis; in this instance, both. The effect of the growing cysts is about the same as if you were to remove three-fourths of the patient's kidney tissue. It is the quantitative reduction in the number of functioning nephrons which accounts for the polynuria, inability to concentrate urine, and renal failure.

Dr. George Fahr: This child developed enuresis late in childhood, at eleven years of age. Now, when a child develops enuresis at eleven years, you look for something very simple. You don't just call it enuresis. What the child had was polyuria. Being a child she would sleep through the micturition period. She had just what you find in the stage of chronic renal insufficiency when the patient is approaching uremia. The first thing that you should do is to take a careful check of the specific gravity of the urine. If you see such a patient in the right state, you also practically always find hypertension. In the early stages, the urine may show a little albumin in a catherized specimen. You don't find white blood cells or red blood cells un-

less they have sudden hemorrhages. This is a paroxysmal thing. Later in the disease pyelonephritis may develop and then the urine will contain albumin. This child had little albumin and very few white blood cells at first. Then you notice that something happened; she ran a fever, rising leukocytosis, and now pus cells were seen in the urine. About the same time she got the parotitis and her pleurisy symptoms that later turned out to be empyema. I think that the pyemia originated from infection of these cysts.

ACUTE PORPHYRIA

W. H. FORD, M.D., and H. L. ULRICH, M.D.
Minneapolis, Minnesota

PORPHYRIA is not an extremely rare disease, but the diagnosis may be missed even after careful study and autopsy. Three cases of porphyria have been found in Minneapolis in the last five months. The diagnosis in our case was made only because of the red urine, which showed the typical spectroscopic bands of porphyrin. Spectroscopic examination was made by Dr. C. J. Watson at the University Hospital.*

Family history and past history were irrelevant except for three attacks similar to the illness described below.

The symptoms were abdominal cramps, nausea, vomiting, constipation, oliguria, pain in the back, legs, feet, arms, and hands, weight loss, muscular weakness, dyspnea, and difficulty in swallowing. The illness lasted about two months, and the patient died a respiratory death.

Physical examination showed a well-developed, poorly nourished, lethargic, white female with normal temperature, rapid pulse, and a blood pressure of 135/100. There was some drooping of the right eyelid, and a purulent nasal discharge. The shoulder girdle muscles showed marked atrophy and almost complete paralysis. The heart sounds were normal. There were a few râles in the chest. The abdomen was slightly tender. The patellar reflexes were absent. The abdominal reflexes were present.

Radiographs of the lumbar spine, pelvis, chest, head, and neck were negative.

The urine was red; specific gravity 1.012, acid reaction, very faint trace of albumin, faint trace of sugar, very occasional hyaline cast and granular casts, occasional epithelial cell, and a few red blood cells and white blood cells. Spectroscopic examination of the urine showed porphyrin.

The hemoglobin was 72 per cent; the red blood cell count 3,640,000. The white blood cell count, differential count, Kline test, blood calcium, blood phosphorous, basal metabolic rate, and spinal fluid were normal. The stool specimen showed pus and mucus. The blood urea was 80 mgm. and blood urea nitrogen 37.38 mgm.

The post-mortem study of the body, the brain, sections of the spinal cord, and the peripheral nerves was essentially negative.

Jan Waldenström[1] has reviewed the chemical and clinical studies of one hundred cases of porphyria. The clinical manifestations exhibit themselves in abdominal symptoms, particularly in colic and obstipation, changes in the blood, hypertension, disturbances of liver, kidney and metabolism, also marked nervous symptoms.

He grouped them as follows:

1. Congenital porphria (Günther's disease). These patients have porphyria in the urine as infants and their skin is sensitive to light. In many cases the disease is familial (recessive type).

2. Cutaneous porphyria (tarda). These cases occur later in life. There is porphyria in the urine. They are sensitive to light and there is a tendency to sclerodermatous changes. They have colicky symptoms. Uroporphyrin i'i'i' is found in the urine.

3. Porphyria acuta; with variable symptoms.
   (a) Latent type, with no symptoms. Found in members of families in which acute porphyria occurs.
   (b) Pure abdominal forms.
   (c) Pure nervous forms; very frequently they have abdominal symptoms.
   (d) Classical porphyria; with colic and paraplegias.
   (e) Comatose types; in which the terminal event is a coma. It begins with abdominal symptoms. There are no paraplegias.

4. The toxic paraplegias. These are not easily classified. Since they are not to be differentiated from the idiopathic, this group should be abandoned.

The condition must be differentiated from neuroses, psychoses, encephalitis, multiple neuritis, Landry's paralysis, periarteritis nodosum. The commonest confusion occurs in acute abdominal symptoms, particularly where there is pain, fever, constipation, vomiting and leukocytosis. In all acute abdominal symptoms, and in cases which present puzzling neurological data, think of porphyria. He records twenty-nine patients undergoing abdominal operation, the mistaken diagnosis being appendicitis in sixteen, ileus in seven, pelvic conditions in four, choleocystitis in two. Gastric or duodenal ulcers have also been erroneously diagnosed. He has never been able to find porphyrin in any other disease.

The therapy which is more or less futile consists of diuretics, alkalies, intravenous morphia or papaverine, calcium and heat. Sedatives, particularly bromides, should be avoided.

The prognosis: In full blown cases, 80 per cent are fatel. The recurrent abdominal type is much less dangerous.

Of his one hundred cases, twenty died within one year from the appearance of the symptoms of the disease. Only two lived eight years. Of twelve known living cases, one has gone on for twenty-seven years.

*The detailed description of the porphyrins encountered in the urine of this patient will be included by Dr. Watson in a separate report.

HISTORY OF MEDICINE IN BROWN COUNTY

Compiled by George B. Weiser, M.D.

(Continued from March issue.)

Physicians at Sleepy Eye

Dr. W. Town practiced in Sleepy Eye in 1873 and 1874. He ran a drug store for a time.

Dr. J. W. B. Wellcome, whose biography appears under the head New Ulm Physicians, practised in Sleepy Eye for a time.

Dr. Fred Wellcome studied medicine under the supervision of his father, Dr. J. W. B. Wellcome, and opened an office in Springfield in 1874. He later gave up the practice of medicine and engaged in the real estate and banking business in Minneapolis.

Dr. T. M. Marcellus, born in Canada, in 1852, came to the United States in 1866 and resided at Northfield, Minnesota, twelve years. He was a student at Carleton College, then went to the University of Michigan, where he graduated from the Medical School in 1878.

He located at Sleepy Eye where he practiced several years, then moved to Overton, or Charlottsville, Albermarle County, Virginia, in 1895. He died in 1908.

Dr. Harper M. Workman, born in Circleville, Ohio, 1858, graduated from the University of Chicago Medical School in 1880. He located at Sleepy Eye about 1880, having been sent there by the chief surgeon of the Chicago & Northwestern Railway, as surgeon for the construction gang. When the railroad was being built to Pierre, South Dakota, the division point was moved to Tracy in 1882, where he established his practice. He continued practicing his profession until his death, October 8, 1936.

Dr. Workman was first president of the village council of Tracy. He was a member of the Tracy School Board for twenty years; was president of the Council of the Minnesota State Medical Association for twenty years, to the time of his death, October 8, 1936, and was past president of the Association.

Dr. Workman took an active interest in his county and state societies; in both he was an indefatigable worker and a faithful servant.

Dr. Novious came from Sauk Center to Sleepy Eye in 1887. He was a partner of a Dr. Von Eschen.

Dr. A. P. Poaps, born in Montreal, Canada, in 1859, entered Kingston College of Physicians in 1877, then went to Bellevue Hospital Medical College, graduating in the spring of 1881. He located at Sleepy Eye in August, 1881, practiced there a brief period of time, and then moved to Los Angeles, California.

Dr. H. Wechsler practiced in Sleepy Eye in 1885.

Dr. Jacob B. Wellcome, Jr., son of Dr. J. W. B. Wellcome, graduated from St. Louis College of Physicians in 1890. He commenced the practice of medicine in Sleepy Eye the same year and continued there until the time of his death, January 3, 1935. He served as mayor and was local surgeon for the Chicago & Northwestern Railway.

Dr. James McPeek, graduate of Keokuk Iowa Medical School, 1889, practiced at Sleepy Eye for a brief period.

Dr. A. Franklin Strickler, whose biographic sketch appears under New Ulm physicians, located at Sleepy Eye in the year 1900.

Dr. Mary Strickler, wife of Dr. A. Franklin Strickler, was born in Dodge Center, Minnesota, in 1873. She graduated from the University of Minnesota Medical School and was associated with her husband in the practice of medicine at Sleepy Eye. After her husband's death she continued practicing until 1935, when she retired. She now resides at Medford, Oregon.

Dr. J. S. Kilbride, graduate of the University of Illinois Medical School in 1892, located at Sleepy Eye for practice of his profession. He later moved to Canby, Minnesota, thence to Worthington, where he resides at the present time. His son, Dr. E. A. Kilbride, is located at Worthington where he is engaged in the practice of medicine.

Dr. Ernst O. Pucklitsch, a graduate of Miami Medical College, Ohio, located in Sleepy Eye in 1894. He practiced there until 1898, when he moved to Cincinnati, Ohio, his former home. He was a member of the Brown County Medical Society.

Dr. N. C. Davis, a graduate of the College of Physicians and Surgeons, Keokuk, Iowa, practiced in Sleepy Eye in 1896. After one year he moved to Pipestone, Minnesota, where he had previously practiced for five years.

Dr. M. A. Kiefer, born at Beaver Falls, Minnesota, March 29, 1878, graduated from the University of Minnesota Medical School in 1904. He located at Sleepy Eye where he continued the practice of medicine until his death in 1931.

Dr. Gottfried Schmidt, born in Minnesota in 1871, graduated from the Minnesota Homeopathic Medical School in 1903 and located in New Ulm the same year. He moved to Sleepy Eye and engaged in practice there for several years, then moved to Lake City, Minnesota, where he continued practicing medicine until 1940. The State Board of Medical Examiners suspended his license for a period of five years for irregular practice.

Dr. A. P. Goblirsch, graduate of the University of Minnesota Medical School, 1925, served his internship at Ancker Hospital, Saint Paul, and one year of postgraduate work at Ancker Hospital.

In August, 1926, he located in Sleepy Eye where he has been engaged in the practice of medicine to the present time (1940).

Dr. William O. McLane and **Dr. Evelyn McLane,** both graduates of the Medical Department of the University of Minnesota, located at Sleepy Eye about 1930. The latter part of 1933 they moved to Jackson, Minnesota, where they reside at the present time.

Dr. J. L. Ryan, a graduate of Marquette Medical School, 1934, formerly of Snilsberg, Wisconsin, located in Sleepy Eye in 1934. He moved to Philadelphia in the year 1939, and is now taking a course in obstetrics and gynecology at the University of Pennsylvania (1940).

Dr. C. R. Senescal located in Sleepy Eye in 1932 and has been in practice there since that time.

Dr. E. W. Wohlberg, a graduate of the University of Minnesota Medical School, located in Morgan, Minnesota, for a brief period, then moved to Sleepy Eye in 1939. He is engaged in the practice of medicine there at the present date (1940).

Physicians at Springfield

Dr. Jacob C. Rothenburg, whose biography appears under the head of New Ulm Physicians, located there before locating at Springfield. He died in 1939.

Dr. Harvey A. Hitchcock settled in Springfield, Minnesota, in 1878. He was born in Courtland County, New York, studied medicine in Janesville, Wisconsin, and attended a medical institute in Cincinnati, Ohio. He practiced in Janesville, Wisconsin, and Morristown, Minnesota, before coming to Springfield. He moved to California in 1881.

Dr. Thomas Sullivan, born September 7, 1857, was one of the early physicians of Springfield. A graduate of the University of Toronto, 1881, he first located in Sharon, Pennsylvania, then moved to Springfield in 1883. He practiced medicine at Springfield until the time of his death, November 9, 1905. He was a member of the school board for many years.

Dr. J. S. Schrader, born March 9, 1858, in the County of Niagara, New York, received his preliminary education at Clarence Academy, New York. He graduated from the Medical Department, University of Michigan, in 1885. In 1901 he spent six months in postgraduate work in Vienna, Berlin, Paris and London.

He commenced the practice of medicine in Hadley, Michigan, where he remained six months, then located at Delano, Minnesota. He practiced there for fifteen years, then moved to Springfield and formed a partnership with Dr. J. C. Rothenburg, which was dissolved in 1932. From 1932 to 1940 he practiced at Hollendale, Jordan and Marietta, Minnesota, then returned to Springfield in the early part of 1940. During his medical career he has served as a member of the Pension Board at Buffalo, Minnesota, also as a member of the State Board of Medical Examiners for several years.

Dr. Cleveland Friederichs, born October 29, 1889, at Elgin, Iowa, graduated from the New Ulm high school in 1904. He received his M.D. degree at Northwestern Medical School, then located at Springfield in the summer of 1909. He practiced there until his death, October 24, 1911.

Dr. W. G. Muessle, born in 1889, graduated from the University of Minnesota in 1913. He located at Springfield about the year 1916, and has been in continuous practice there ever since.

Dr. W. A. Meierding, a native of Brown County, Minnesota, graduated from the University of Minnesota Medical School in 1907. After graduation he became a member of the medical staff of the State Hospital, Fergus Falls, 1909-1910. He located at Buffalo, South Dakota, 1910-1911; then at Springfield, Minnesota, 1911-1917. He was a captain in the World War, 1918-1919. He located in New Ulm in 1919, and served as secretary of the Redwood-Brown Medical Society from 1920 to 1934. In 1934 he retired from the practice of medicine and moved to Norco, California, where he now resides.

Dr. Edwin John Wohlrabe, born November 16, 1899, at Truman, Minnesota. He graduated in 1925 from the University of Minnesota Medical School, and served an internship of eighteen months at Philadelphia General Hospital. His first location was in New Ulm, August, 1926. In December of that year he moved to Springfield, where has been in continuous practice ever since.

Dr. Clarence F. Wohlrabe, born December 28, 1897, at Truman, Minnesota; graduated from the Mankato high school, then entered the University of Minnesota Medical School, graduating in 1924. He finished his internship in 1925, and opened an office for the practice of medicine in Young America in December. He formed a partnership with his brother, Edwin J. Wohlrabe, at Springfield in 1926, continuing there till 1933. He then moved to Minneapolis where he practiced until 1939. He is now located at North Mankato, Minnesota.

Dr. J. Emory Frank first located in Springfield about 1935, then moved to Marshall, Minnesota.

Dr. C. B. Abbott located at Springfield, Minnesota, about the year 1930, and has been engaged in the practice of medicine there to the present date (1940).

Dr. E. R. Penk, who came to Springfield in 1937, is still engaged in the practice there.

Physicians at Comfrey

Dr. Joseph A. Prim, graduate of the University of Minnesota Medical school, 1899, located at Comfrey where he practiced for several years. He moved to Minneapolis where he resides at present, practicing medicine. He was succeeded by Dr. H. D. Herron.

Dr. H. D. Herron practiced medicine at Comfrey until 1916, when he was succeeded by Dr. Arthur W. Eckstein.

Dr. Arthur W. Eckstein was born in New Ulm, and graduated from the New Ulm high school in 1906. He graduated in pharmacy at the University of Minnesota in 1908; in medicine at the Northwestern Medical College, Chicago, in 1912.

He first located in St. Cloud, then moved to Holdingford, where he practiced from 1914-1916. He practiced at Comfrey from 1916 to 1928, then located in North Mankato where he resides at the present time (1940).

Dr. F. C. Gibbon, who succeeded Dr. Eckstein at Comfrey in 1928, graduated from the University of Minnesota Medical School in December, 1926, and served his internship at the Minneapolis General Hospital, 1927. He first located in Springfield but moved to Comfrey in December, 1928. He has been engaged in the practice of medicine there ever since.

Physicians at Hanska

Dr. Douglas F. Wood, a graduate of McGill University, Canada, was the earliest practicing physician at Hanska, where he remained until 1909. He was appointed by Governor Johnson as a member of the State Board of Medical Examiners. After leaving Hanska he took postgraduate work in Vienna to specialize as an aurist and oculist. He practiced his specialty in Minneapolis until his death in 1934.

Dr. S. P. Seaburg located in Hanska in 1908 and remained their four years.

Dr. Dahl, graduate of a medical school in Norway, practiced at Hanska for a brief period of time. He then moved to North Dakota.

Dr. Mathias Sundt, born in Norway December 10, 1882, graduated from the Medical School, University of Minnesota, in 1909. He located in Hanska, where he was engaged in the practice of medicine until 1920, when he moved to Minneapolis, associating himself with the Sivertsen Clinic.

Dr. E. Borgeson located in Hanska about the year 1921, then moved to Minneapolis. Graduated from the University of Minnesota in 1920.

Dr. O. F. Pederson located in Hanska about the year 1923. He practiced medicine there until 1932, when he was succeeded by Dr. W. Donald Graham.

Dr. E. G. Olmanson, graduate of the Northwestern Medical School, located in Hanska for a brief period, then moved to Saint Peter, Minnesota.

Dr. H. Mortensbak, graduate of the University of Minnesota Medical School, 1934, located in Hanska and is practicing medicine there at the present time (1940).

(To be continued in May issue.)

FREEDOM TO THINK

We all pass through a stage of thinking that our generation in its day was a little wiser than the one that followed it. In this we are doubtless very often wrong, but I believe that my generation of medical students was more alive to the uses and interests and educational value of the debating and scientific criticism than the generation that came between the two great wars. Make every use of your opportunities here. Learn to speak in public and test for yourselves the mental stimulus of logical dispute.

You cannot afford to school yourselves in science alone. You must know something of men and movements, too. You must qualify for citizenship as well as for your baccalaureate or doctorate in medicine. Whatever form our future state may take the doctor will always be a key man in its organization. He must earn his freedom to think and to advise and must seek by every means in his power to become, like Grenfell of Labrador, like Balzac's "Country Doctor," like many a good physician who dies unsung after an arduous life devoted to the community, a man of ideals, a man of judgment and a man of action.—JOHN A. RYLE: *Cambridge University Medical Society Magazine,* Michaelmas Term, 1940.

President's Letter

NATIONAL DEFENSE

TODAY the man on the street and in the office, the worker in industry and the worker on the farm, the professional man and the merchant, all talk the same language and about the same thing—National Defense.

Those of us who had a part in the first World War know how intimately each one was gradually drawn into the maelstrom and how each family in the land was affected one way or another at some time during those trying yeârs.

That the men of medicine are doing their share without fear or favor this time as in the past goes without saying. The national emergency overshadows any feeling of personal loss or gain. We are conscientiously producing, through our culling by examinations of selectees, volunteers and National Guard, as fine a manpower for the Army as can be found in any country. Serving without pay as local draft board examiners, members of Medical Advisory Boards and draft appeal boards, we are spending our time as well as our money to further the cause. In induction centers we find men working for small pay, $15.00 a day, who, if they spent the same amount of time in their private offices, would be compensated many times more for this time. They are doing their part.

About two hundred of the Medical Reserve Corps in our state have already been called for active service. A hundred and fifty more will be in active work in camps and elsewhere by this coming summer while those who are members of the National Guard are already called to duty. These men have, in most instances, left active practices. They have not been found wanting.

Many Departmental Advisory Committees are either headed out by or have physicians as active members on them. The American Medical Association, through its activities, has correlated various departments and is coöperating closely with the War Department.

In all these and many more ways the medical personnel of the country is playing a very important part in the emergency. When history is written in the future, it will, I am sure, show in good light the unselfish attitude of the medical profession.

Each of us should be proud to be a part of this history-making, doing our share to help establish again on an even keel, world economy. It cannot be said now nor will it ever be said of us that we were dilatory in the help which we have given to our government.

B. J. Branton, M.D., *President,*

CLINICAL-PATHOLOGICAL CONFERENCE

IT was the abundance of autopsy material that made Vienna the Mecca for years of the physicians in this country. Known by the Germans as "Die Erklarung," the autopsy answered many a question which had puzzled the clinician. The autopsy is just as important today as it ever was and the recognition of this fact by the profession and the laity alike has accounted for the high medical attainment achieved in this country. It is a number of years since the profession in this country has needed to go abroad for medical study.

The most valuable meetings which the physician located in the large centers attends today are the clinical-pathological conferences. Here the clinical findings are correlated with those found at autopsies and the opportunity is afforded to present every phase of the disease encountered. This fact is not as generally recognized as is should be.

In order that our readers not located in the larger centers of population may share to some degree the benefits derived from such a conference, we are planning to publish again each month a report of at least one case presented at one of the conferences held in the Twin Cities, this time from that held at the Minneapolis General Hospital. The editor would appreciate an expression of the reaction of our readers to the publication of this report. In this way only can we determine whether its continuation is worth the effort.

FOURTH OF JULY INJURIES

WHY mention the Fourth of July in April? Because the subject of Fourth of July injuries is suitable for discussion any day in the year. Perhaps July 4 comes so far in advance of the term of the legislature that everyone has forgotten the injuries from the previous Fourth of July and no one remembers to submit a bill for statewide prohibition of fireworks. We sometimes pass our laws if and when we think about them.

Minnesota should have a state law prohibiting sale and possession of fireworks except for authorized public celebrations. We shall have the law in our state when public opinion demands it. There is evidence throughout the country that public opinion is predominantly in favor of eliminating the needless injuries—some of them fatal—which follow Fourth of July accidents. It only remains for public opinion to make its demand sufficiently felt. What is more fitting than that the medical profession should start the movement to obtain this beneficial legislation in Minnesota.

Here are some of the facts. Injuries from Fourth of July accidents constituted enough of a problem at the turn of the century so that the

Journal of the American Medical Association made yearly summaries of the number and nature of these accidents from 1903 until 1916. The reduction in injuries became so marked that the tabulation was discontinued. In recent years these injuries have been on the increase, several thousand being reported each year, this representing probably only a small percentage of the total number. The tabulation by the American Medical Association has, therefore, been resumed.

In 1937, there were twenty deaths reported due to burns and explosions incident to Fourth of July celebrations. In 1938, the number was eighteen and in 1939 it showed a reduction to thirteen. This was due to the improvement in the figures reported in Pennsylvania. In 1938, Pennsylvania reported 1,702 Fourth of July injuries and headed the states with six deaths. A state law barring fireworks in Pennsylvania became effective in 1939 and injuries were reduced to 85, and no deaths were reported. This is an outstanding example of the effect of such a state law.

Other figures could be given to show the salutory effect of laws and ordinances outlawing fireworks. In Saint Louis, injuries were reduced from 195 in 1938 to 76 in 1939 by such an ordinance. A perusal of the number of injuries reported from Iowa, Wisconsin, Michigan, and New Jersey, which states are numbered among the nine having prohibitive legislation, shows lower figures in these states than in Minnesota, in spite of prohibitive ordinances in the Twin Cities. Both Minneapolis and Saint Paul have ordinances prohibiting the sale or possession of fireworks within the city limits. For ten days preceding the Fourth of July each year the boundaries of both cities are demarcated by our country's flag flying from a road-side counter selling fireworks. The inconvenience of making a trip to the outskirts of the city doubtless lessens the possession of fireworks and consequent accidents within the city limits, but how ridiculous the situation.

Public opinion within a Minnesota city sufficient to support a city ordinance of this sort is indicative of general public opinion throughout the state and, of course, widespread public approval of such a prohibitive law is essential in order to expect satisfactory enforcement. Local prohibitive ordinances in the Twin Cities have doubtless kept the state as a whole from presenting too grim a picture. Although no deaths have been reported in Minnesota following these seasonal accidents during the years 1937, 1938, and 1939, it is impossible to say how many have been prevented by injections of lock-jaw serum. The report of 146 burns and lacerations, one case of loss of vision, three additional eye injuries, and one lost member from Fourth of July celebrations in 1939 suggests a much larger total number of accidents throughout the state.

Many elements in society should be willing to join forces, as is being done now in Massachusetts, in obtaining legislation to ban fireworks throughout the state, except for properly supervised public exhibitions. Societies for the prevention of blindness, municipal authorities, fire chiefs, physicians and particularly all parents should be only too willing to support legislation to eliminate that dread of accident which has ever been an accompaniment of the Fourth of July.

CHARLES WARDELL STILES

TO many people, especially those who are not physicians, the news of the death of Dr. Charles Wardell Stiles on January 24, 1941, will mean nothing, for his name was never published in the daily press and he was never awarded any distinction that would have placed him even momentarily in the limelight. He was just one of the host of scientific workers who plod away at their appointed tasks, caring nothing for public acclaim and not raising as much as a finger for notoriety.

He was one of our most distinguished helminthologists. It was his pioneer work in hookworm disease that laid the scientific basis for the splendid public health program which has gone so far in the eradication of that baleful condition. His original contribution under the modest title of Report on Hookworm Disease (Uncinariasis) in the United States in 1903 first brought the subject to attention. The facts he presented attracted the attention of the Rockefeller Foundation and he served as scientific secretary to the Rockefeller Commission for the Eradication of Hookworm Disease from 1909 to 1914. The South owes him a tremendous debt.

While his work was closely tied into that of clinical medicine he never took a medical course.

After two years in Wesleyan University he spent four years in Paris, Berlin and Leipzig, receiving his A.M., Ph.D., from the University of Leipzig in 1890. His chief connection thereafter was with the United States Public Health Service. He taught medical zoölogy for forty years in Johns Hopkins, was U. S. delegate to the International Zoölogical Congresses for a number of years and served as secretary, from 1898 to 1936, to the International Commission on Zoölogical Nomenclature. He was a voluminous writer, almost exclusively on parasitic diseases, and was a member of many American and foreign scientific associations. His death is a severe loss to scientific medicine.

GILBERT COTTAM

AMERICAN ACADEMY OF PHYSICAL MEDICINE

The American Academy of Physical Medicine will hold its Nineteenth Annual Meeting and Scientific Medicint will hold its Nineteenth Annual Meeting and Session on April 28, 29, 30, 1941, in New York, with headquarters at the Hotel Pennsylvania, where lectures, symposia, clinical papers, motion pictures, and the exhibits will be presented. Clinics will be held at the Medical Center, New York Orthopædic Hospital, Post Graduate Hospital, and the Skin and Cancer Hospital. There will be an evening session at the Academy of Medicine Building and a banquet at the Hotel Pennsylvania.

Physical medicine in relation to general medicine and the specialties will be the underlying theme of the topics under discussion. These include new developments in electrotherapy, electro-surgery, radiation therapy, hydrology, physical education, military medicine, aviation medicine, and laboratory reports on related investigation.

The sessions are under the direction of Harold D. Corbusier, M.D., Plainfield, N. J., President; Herman A. Osgood, M.D., Boston, Secretary; Fred H. Albee, M.D., New York, Chairman of the Committee on Arrangements; William D. McFee, M.D., Boston, Chairman of the Committee on Program; William Benham Snow, M.D., New York, Chairman of the Committee on Clinics; and Franklin P. Lowry, M.D., Newton, Mass., Chairman of the Committee on Exhibits.

All members of the medical profession and those of related interests are invited to attend the scientific program. There will be no registration fee. Address inquiries to Herman A. Osgood, M.D., Secretary, 144 Commonwealth Avenue, Boston, Massachusetts.

CORRESPONDENCE

Baudette, Minnesota

To the Editor:

This may be of interest to you: I have just returned from a 19,188 mile plane trip. Leaving Fargo, N. D., December 1, I flew to Manila, Philippine Islands, to visit my father, Dr. H. E. Stafford, who has retired and now lives in Baguio, P. I. I found that he has Buerger's disease, and wanted to see him before it was too late. It was my Christmas present to him, and quite a surprise, for he did not know anything about my plans until I wired him from Guam Island. The transpacific flight was quite interesting, though I was marooned for three days on Wake Island, waiting for a couple of typhoons to get out of the way, and also, on the third day, we took off, only to return in half an hour on account of engine trouble.

The Islands are frankly quite worried about Japan. Guam is pitifully unfortified, though at Midway, considerable work is being done to fortify the island and make a plane base out of it. Similar work was just starting at Wake Island. As we see by the papers, Guam is finally getting the money for defense work. Japan, for years, has quite successfully hoodwinked the United States out of any defense program, along with our misplaced economy-spending programs of the past ten years. The Filipino is at last casting longing glances at the United States, though he still kids himself a la independence.

Incidentally, I was born out there, way back when, and this happens to be my first visit to Manila in fifteen years, and the first visit to Baguio in twenty-two years. I succeeded in taking about 700 feet of colored movies, most of which came out on top. No movies or photography with a camera can be taken while on the Pan-American Clipper—Navy regulations. And absolutely ditto no on Wake and Midway Islands. I went through the Navy hospital at Guam. They have a lot of amebic liver abscesses and tuberculosis is on the rampage. The boys are doing good work there. I met a Minnesota graduate, but cannot remember his name. Both Midway and Wake have Pan-American medicoes, good men, military field equipment, and are within twelve to thirty-six hours from a hospital by airplane (Honolulu). Wake Island, size of about thirteen blocks, has a current population of twenty-seven, no women. The boys sadly need anaphrodisiacs.

Sincerely,

February 27, 1941 CHARLES C. STAFFORD

Health and National Defense

The need of national defense reqnires a strengthening and broadening of the entire industrial health program all along the line from private industry to local, state and federal jurisdictions. In this significant period of re-armament, during which our chief defense will be our industrial skill, let us be sure that we place first on our list the health and safety of our industrial workers.—L. D. BRISTOL, M.D., Jour. A.M.A., Oct. 12, 1940.

MEDICAL ECONOMICS

Minnesota State Medical Association
George Earl, M.D., Chairman

INSURANCE OF THE EXPENSE OF MEDICAL SERVICE*

WENDELL A. MILLIMAN

NOTE—*Mr. Wendell A. Milliman is Associate Actuary of the Equitable Life Assurance Society of the United States. This article appeared first in the 1940 Transactions of the Actuarial Society of America. It is reprinted here through the courtesy of the author and of the Actuarial Society because prepaid medical service and medical expense insurance are of great current interest to all physicians, and also because this is the first authoritative analysis by a recognized actuarial expert to come to the attention of the Committee.* —THE EDITORS.

CONSIDERABLE literature concerning the subject of "health insurance" and the cost of medical care has grown up during the past few years, indicating the increasing public interest in the problems created by the heavy and unpredictable incidence of the cost of medical care. Most of the writers on this subject have approached the problem from the standpoint of either the social economist or the physician. The typical conclusion of the social economist is that the faults of our present system of distribution of medical services can be cured only by the adoption of a program of compulsory "health insurance." The physician normally regards any proposal of compulsory "health insurance" as a threat to the very foundation of sound practice of medicine. Between these two violently opposed viewpoints has gradually developed the idea that a system of voluntary insurance of the expense of medical service can be developed without disturbing the present profession relationship between patient and physician. The importance of this viewpoint is illustrated by the fact that during 1939 Connecticut, Michigan, New York, Pennsylvania and Vermont enacted laws permitting the organization of nonprofit corporations to operate medical service plans on a prepayment basis.[1] The author does not wish to use this opportunity to quarrel with either of the extreme viewpoints, or to act as a proponent for the middle course. In this article it is hoped to survey in an objective manner some of the developments of this middle course, with particular emphasis on those aspects which appear to involve elements of insurance or with respect to which insurance experience should prove of value in indicating desirable action. Space limitations obviously prevent full discussion of all of the aspects of the many problems of public health and medical economics that are touched upon in this paper. Equally obvious is the author's lack of qualifications to discuss all of these many and varied aspects. The reader's indulgence is therefore requested if, in the process of approaching these problems from the standpoint of insurance, conclusions are reached which are at variance with those which would result from other approaches.

The recent widespread development of hospital expense insurance through the medium of nonprofit hospital associations, through group insurance policies, and through individually issued policies, has increased the interest in the voluntary insurance approach to this problem. The insurance of the expense of physician's services is apparently being developed along similar lines, i.e., by nonprofit associations, through group insurance, and through individually issued policies.

Insurance of medical expenses is not an entirely new idea in this country. Aside from the extensive benefits provided under workmen's compensation coverages, insurance companies have offered limited benefits for some time, and in recent years there has been a tendency to

*Unless otherwise indicated by the context, the term medical service is used in this article in a restricted sense to include only the services of physicians.

broaden the scope of such coverages. Personal accident and health insurance policies have for many years provided limited surgical indemnity benefits. In 1930 or 1931 several companies offered, at an extra premium, an optional additional benefit in personal accident insurance policies, consisting of a very liberal medical expense indemnity provision under which all hospital and medical expenses incurred by the policyholder in the treatment of his injuries are insured, subject only to an aggregate limit with respect to each accident, of $500 or some greater sum.[2] This benefit is quite generally offered today. Since early in 1938 many companies writing group insurance have offered a surgical insurance benefit as an optional additional benefit to be included in group hospitalization policies. Further reference to this benefit will be made later.

Besides this activity of insurance companies a considerable amount of experimentation has been undertaken by various other groups interested in the problem of providing medical service.[3] These experiments are extremely varied both in details and in basic philosophy. Several plans are briefly described below in order to illustrate the range of this variation.

The plan of the Brattleboro Memorial Hospital Association is practically unique in that it is limited to the insurance of the expenses of serious illnesses. Despite its relatively recent origin —it was organized in 1927—it is one of the pioneer organizations in this field. The association insures hospital expenses, and surgeons' fees, in excess of the sum of $30 for each illness and subject to a maximum benefit ranging from $150 to $300 for illness requiring surgery, depending upon the premium rate charged the member, and one-half such maximum if no surgery is required. The annual premium rates per individual are shown in the accompanying table.

	Maximum Benefit		
	$150	$200	$300
Adult subscribers (including husbands and wives of subscribers)	Per person $5.00	Per person $6.66	Per person $10.00
Adult dependents (other than spouse of subscriber)	3.90	5.80	7.80
Children, ages 16 to 21	5.00	5.00	5.00
Children under age 16	3.00	3.00	3.00

The association has no contracts with the surgeons who render service, but since all such service must be rendered in the Brattleboro Memorial Hospital, reasonable control over the surgeons' fees is exercised. The membership of the association is quite restricted due to the size of the community in which it operates. At April 1, 1940, there were 3,359 persons insured by the association.

Another plan which involves elements of insurance is the King County Medical Service Bureau (Seattle, Washington) which was established in May, 1933, under the sponsorship of the King County Medical Society. It offers medical, hospital and nursing service for a period not exceeding twenty-six weeks with respect to any one illness or accident, including occupational accidents. The plan permits the patient free choice of physician within the group of 450 participating physicians. The physicians are reimbursed upon a fee-for-service basis, the payment being subject to pro-rata reduction if necessary to preserve the solvency of the organization. Membership is limited to employed persons who enroll in minimum groups of six, representing at least 75 per cent of those eligible for enrollment. There are at present approximately 40,000 persons covered by the plan. The premium rates vary from $1.25 to $3.50 per month per employe, depending upon the compensation rate for the industry.

The foregoing organizations insure, to a greater or lesser extent, the cost to the individual, but do not disturb to any material extent the present, almost universal, basis of payment to the physician for the services he renders. This basis of remunerating the physician is commonly described as the fee-for-service basis. The arrangement included in the King County plan for pro-rating such fees is known as the unit disbursement system. Employment of a physician, or physicians, by a central agency on a salary basis, or payment to the physician of a fixed annual "capitation" fee for each potential patient on his "panel" are the two other methods widely used to furnish medical service at a fixed annual price to the consumer. These methods do not involve insurance in the normal sense,

although it will be seen that the physician must, within limits, bear the burden of large demands for service, or benefit from light demands for service.

The Ross-Loos Medical Group, operating in the Los Angeles area, is an outstanding example of the employment of physicians on a salary basis for the purpose of furnishing medical service to subscribers at a fixed cost. The group was organized in 1929 as a clinic to provide to employed subscribers complete medical and surgical treatment, hospitalization, and, to a limited extent, medicines and supplies. In addition it provides similar services to dependents of subscribers at substantially reduced rates. The clinic is operated as a partnership of eighteen physicians, and has a total staff of seventy-five full time physicians. There were, at December 31, 1939, 22,983 subscribers. There were in addition approximately 50,000 dependents of subscribers entitled to service at reduced rates.

The cost to employed subscribers enrolled on a group basis is $2.50 a month while the cost to subscribers enrolled on an individual basis, with direct payments of premiums, is $3.00 a month. Dependents of subscribers are entitled to services other than hospitalization at reduced charges. (A dependent is defined as one who is permanently and completely dependent upon the subscriber for support, who resides in the same house, and who is related to the subscriber by blood or marriage.) The reduced charges for dependents are $.50 for each office call, $1.00 for each residence call, and other small charges for special procedures, such as $25 for a major operation.

The employment of physicians on a panel system is illustrated by the plan of the City Central Committee of the International Workers Order of New York. Through its medical department this fraternal society has since 1930 provided medical service to members (and their families) at an annual cost of $2.70 per year for single members and $4.20 for families. A family includes husband, wife, and children under eighteen. The medical service provided is that of an annual physical examination, office and home calls of a general practitioner, and services of specialists at reduced rates. The general practitioner, or district physician, is entitled to charge minimum fees for after-hour calls, for minor surgery, and for obstetrics. The annual capitation fee paid by the Order to the district physician is $1.80 per single member, and $3.00 per family. No additional remuneration, over the fees paid directly by members, is paid to the specialists. At December 31, 1939, approximately 15,000 members were participating in the Medical Department, so that, including dependents, approximately 60,000 persons were entitled to the benefits of that department.

Numerous instances could be cited of the provision of complete medical service for a group of employes through the employment of a physician, or physicians, by the employer. Since these plans normally entail no expense to the potential patient for such medical service, they have no direct bearing upon this discussion. There are also numerous instances of provision of medical service for relief groups upon plans based upon new methods of compensating physicians for their services. These experiments have illuminated some of the administrative problems which would be involved in any community-wide voluntary plan, and reference is made in a subsequent section to some of the experience with such problems.

The various plans briefly outlined above indicate the great variation in the plans of medical expense insurance which have been proposed or adopted. As previously indicated, group insurance has been extended into this field to a limited extent. On the other hand, there are numerous other organizations actively interested in establishing comprehensive plans of insurance of medical expenses, or of otherwise distributing medical services at a fixed annual cost. Both types of approach will be discussed in this paper with particular emphasis on these latter comprehensive plans.

The interest of those seeking a workable solution to this problem is usually occasioned by some one or more of the following desires:

1. A desire to eliminate the uneven burden of the cost of medical care.

2. A desire to find a workable substitute for compulsory health insurance.

3. A desire to improve the quality of medical service.

The purpose of the present paper is to explore some of the difficulties in the application of the insurance principle to this problem. Many of these difficulties grow out of the conditions im-

posed by the last two of the above objectives. For instance, the desire to find a workable substitute for compulsory health insurance imposes the necessity of providing a benefit for the lower income groups at moderate cost without resorting to taxation and without reducing the average cost of medical service rendered to moderate and high income groups. It should be noted here that it is traditional with the medical profession to charge for medical service in proportion to the patient's ability to pay. To the extent that the physician is willing to accept smaller fees for his services from persons of smaller incomes, the idea of charging different premiums to persons of different economic circumstances does not theoretically interfere with the application of insurance principles, although it obviously does introduce new and substantial administrative difficulties.

The desire to improve the quality of medical service introduces the idea of preventive medicine in the form of periodic health examinations and early visits to the physician in the event of illness. There can be no question as to the social desirability of more widespread use of periodic health examinations. However, the very fact that the cost of health examinations does not impose an unpredictable financial burden upon the individual takes it outside of the range of insurance as such. Nevertheless, it would seem to be entirely sound to include health examinations in a plan of medical benefits on the grounds that it is a service which can be included without endangering the safety of the plan. The difficulties arising from insurance of the first few visits of a physician will be referred to later.

A fundamental characteristic of an insurable hazard is that the frequency of the happening of the event which is the subject of the insurance should be subject to prediction within reasonable limits of error. A necessary corollary is that the happening of the event must not be subject to the control of the insured individual, or that there must be a strong incentive or normal desire on the part of the insured individual to avoid the happening of the event which is the subject of the insurance. It is equally necessary that the insured event shall be susceptible of precise and easily understood definition.

If the physician is remunerated upon a fee-for-service basis, then, in a sense, both the physician and the patient are insured individuals. While theoretically the frequency of conditions *needing* medical service is not within the control of the individual, it is obvious that the frequency of conditions for which medical service is *sought* is to a very considerable extent subject to this control. The extent of this control varies inversely with the seriousness of the condition needing medical service. Once medical service has been sought with respect to a condition, the volume of service becomes largely subject to the control of the physician, although it is still subject to some control by the individual.

It is apparent that the expense of the first few visits of a physician with respect to an illness or injury is, in the above sense, an uninsurable hazard. Conversely, the inclusion of such benefits in a plan imposes the necessity of strict supervision or some other control in order to minimize, or eliminate, the financial effect of too frequent visits to the physician with respect to minor, or nonexistent, disorders. It thus appears that the event must be limited and restricted if it is to be removed from substantial control by the insured individual or the physician. These limitations and restrictions immediately present difficulties in the matter of obtaining precise and easily understood definitions. The payment of the physician on a caption basis automatically safeguards the finances of the "insurer" and obviates the necessity of such limitations and restrictions. However, if the average volume of service demanded by the patient under such a plan is substantially in excess of that contemplated in the formulation of the plan, new problems arise.

In the following section a few of the practical problems involved in formulating a comprehensive plan of medical expense insurance are discussed.

1. The growing use of x-ray for diagnostic purposes and the temptation to the physician to use such service as a substitute for his own diagnostic skill mark this type of service for special attention. It is probably the most subject, of any service, to an increase in demand if no deterrents to its unlimited use are devised.

2. Obstetrical care is obviously a benefit which is subject to the control of the individual (within certain age and sex limitations), and hence is not strictly an "insurable" hazard. The question as to whether or not a plan can safely

include obstetrical benefits is intimately related to the conditions of enrollment of subscribers. If a representative cross section of the population were included in the plan, the cost of such care would be predictable. This condition is reasonably met when a group of employes, or employes and their dependents, are enrolled, providing a minimum participation of, say 75 per cent of those eligible is required. However, subscribers enrolled on an individual basis would undoubtedly show considerable self-selection with respect to this benefit, even though careful medical selection were exercised. The effect of this selection can be postponed, and perhaps minimized, by requiring a waiting period before obstetrical benefits are available. It would also seem that with respect to those enrolled in any year this self-selection would tend to disappear within a few years after enrollment. (If a waiting period for obstetrical benefits is used, due allowance should be made for this fact in evaluating the experience of the plan, and some reserve should be maintained for the delayed cost of obstetrical benefits.)

3. In pediatric care, perhaps more than in the care of adults, it is difficult to divorce preventive from therapeutic service. The volume of preventive care in the early years of life undoubtedly has a very marked relationship to the frequency and severity of subsequent illnesses, and the need for therapeutic service. It should be noted that according to accepted standards of proper medical care the frequency of visits to the physician for preventive care is very high in infancy and decreases with advancing age. Here again, attention should be called to the previous remarks concerning the "insurable" character of health examinations.

4. Refraction of eyes for individuals with impaired vision is of a recurring and predictable nature. The comments with reference to the "insurable" character of annual health examinations apply with equal force to eye refractions.

5. Psychiatric care, treatment of tuberculosis and of alcoholic or drug addiction may require very extended service, but such service is in many instances available through public institutions at no expense to the individual. The heavy burden of the cost of such service, when obtained through a private practitioner, makes it a desirable subject for insurance. However, to the extent that adequate service is provided at public expense it would seem unnecessary to insure it. The decision with reference to inclusion, or exclusion, of the expense of medical care for these conditions need not necessarily be the same for each of them.

6. The services of a specialist for a consultation normally command a higher rate of compensation than do ordinary visits of a specialist. Any such expensive service which can be ordered by the attending physician without direct financial burden upon the patient, and without any objective criterion as to what circumstances furnish adequate justification for requiring the service, appears to strain the requirements of an insurable hazard.

7. Laboratory service may be furnished by a commercial laboratory not operated by a physician, or may be furnished by a pathologist. The pathologist is a licensed physician, and hence can perform a broader function than the lay laboratory operator, but naturally commands a higher rate of compensation. The decision as to which type of laboratory service to include would be influenced by the sponsorship of the insuring organization. An organization sponsored by physicians would naturally emphasize the professional character of laboratory service furnished by pathologists, whereas a consumers' coöperative would emphasize the lower cost of the commercial laboratory.

If the furnishing of medical care fully met the criteria of an insurable hazard, which were mentioned earlier in this article, there would not be any necessity for administrative controls. The fact is that both physician and insured can, and, do, influence the quantity of medical care rendered. Perhaps this weakness is characteristic of all types of "insurance" which involve disability, regardless of whether the benefit is indemnity for loss of time, indemnity for cost of hospital service or indemnity for cost of medical care, the difference being one of degree, not of kind. In those plans where the physician is paid an annual capitation fee this fact is of no direct financial importance to the "insurer" since the risk of fluctuation in volume of service is shifted to the physician. This system removes the incentive for the physician to render unnecessary service, and gives him an incentive for discouraging unnecessary demands for service by patients on his panel. By the same token it places great confidence in the professional conscience

of the physician to ensure the rendering of adequate service under these conditions.

When the physician is paid on a fee-for-service basis this automatic protection of the finances of the insurer is absent. It is common for organizations using this basis of compensation to include in the physicians' contracts an agreement to accept pro-rata payment of fees from the funds of the organization available for such payment, i.e., what we have termed the unit disbursement system. But obviously no such organization can continue to operate successfully if the payments to conscientious, honest physicians are substantially reduced in order to pay large amounts to those physicians who make unwarranted claims upon the common fund.

Numerous types of control have been suggested. All are based upon a continuous, or periodic, examination of the individual physician's pattern of practice. This examination may be made by an officer of the insurer, by a committee of physicians, or by purely statistical analysis. When unwarranted claims are indicated there may be merely an adjustment of those claims, or stronger disciplinary action such as cancellation of the physician's contract.

Control based solely upon separate examination of the records of individual physicians, whether by an officer of the insurer or by a committee of physicians, has proven unsatisfactory. Statistical measures of the relative frequency of treated patients, the relative average number of visits per patient, and the relative distribution of types of service have been used for several years in the administration of medical relief in Essex County, Ontario, Canada.[4]

This plan provides for distribution of per capita allowances from the Government of Ontario to the participating physicians upon a fee-for-service basis under the unit disbursement system. The fee schedule provides $2.00 for office calls, $4.00 for night home calls and $3.00 for other home calls. For each month the number of patients treated by each physician is compared with the number of "expected" patients determined from a formula fitted to the experience of the month by the method of least squares. A similar comparison is made of the number of visits by each physician, substituting in this calculation the "expected" number of patients, plus the probable error, if less than the actual number. The total of fees claimed is then adjusted if it exceeds the average fee multiplied by the allowed number of visits. Presumably, consistent excess deviations in the practice of any physician are brought up for review and possible disciplinary action.

The problem of supervising doctors, and disciplining those found to be imposing upon the insurer, is a familiar one in workmen's compensation insurance. It has been at least partially solved in New York by placing the responsibility for such supervision upon the medical profession, through the medium of a committee appointed by the state medical society, as opposed to placing that responsibility in a non-professional body such as the insurer. The experience under this law makes it appear that the medical profession does not welcome supervision by any outside authority, but is reasonably conscientious in self-discipline when the proper mechanism is available.

To the extent that the medical services covered are really insurable, these administrative controls should be unnecessary. Probably the most insurable medical services are surgical procedures, on the one hand, and medical services in treatment of injuries received in an accident, on the other hand. It is within these fields that insurance companies have found it most feasible to enter the field of insuring the cost of medical expense.

Probably the most experimental large scale entry of insurance companies into this field was the introduction on a group insurance basis, early in 1938, of a surgical insurance benefit not confined to accidents. Group surgical benefits were introduced simultaneously with an extension of group hospitalization benefits to permit inclusion of dependents, i.e., wife and children under eighteen years of age. The benefit was first limited to surgical procedures performed in a hospital, but was later liberalized so as to insure the cost of surgery performed either within or outside a hospital. The insurance is a reimbursement benefit subject to maximum amounts of reimbursement with respect to various types of operations. These maximums were fixed to roughly represent the standard minimum fees which could be expected in an average industrial community, and are those widely used at the present time by insurance companies in general. There are variations from this schedule, both as to the inclusion or exclusion of individual

items and as to the maximum amounts of indemnity payable for various operations. In addition, the benefit will be issued providing lower schedules of indemnities, all amounts being reduced proportionately.

Some companies limit the benefit to the specified operations, while others make provision for non-scheduled operations. Such provision is usually limited to cutting operations, and in some instances to cutting operations performed in a hospital. These restrictions arise from the necessity of clearly defining the insured hazard. The line of demarcation between surgical operations and other medical procedures unfortunately is not as sharply and easily defined as is commonly believed. This vagueness is illustrated by the following definition of a surgical operation included in Webster's New International Dictionary.

"A procedure on the living body, usually with instruments, especially for the purpose of restoring health or alleviating suffering."

Since the majority of conditions requiring hospitalization also require some surgery, this problem was of no great moment so long as only hospitalized operations were covered. But when procedures performed in the physician's office or the patient's home were covered, the problem of distinguishing between minor, non-cutting surgery and non-surgical procedures became important.

No adequate statistical basis was available to determine the appropriate rates either for the hospital limited surgical benefit or for the more liberal benefit currently offered. The rate for the benefit limited to hospitalized surgery was computed by one company upon the assumptions that the average surgical fee under the $150 maximum schedule would be $50, and that 75 per cent of hospital admissions, other than for child-birth, would involve surgical care. Since obstetrical care was considered as involving a surgical procedure, 100 per cent of admissions for child-birth would be involved. The following table sets forth the basic factors and the details of the calculation.

	Employed Males	Employed Females		Wives		Children under 18
		Excluding Maternity Benefits	Maternity Benefits	Excluding Maternity Benefits	Maternity Benefits	
Assumed annual rate of hospitalization (all causes)	$.07	$.105	$.035	$.14	$.100	$.07
Assumed annual rate of surgical hospitalization	.053	.079	.035	.105	.100	.053
Net annual cost, at average rate of $50 per operation	2.65	3.95	1.75	5.25	5.00	2.65
Gross annual cost—loaded 1/3 of gross	3.98	$8.55		$15.38		3.98
Monthly premium (taken to nearest 5c)	.35	.70		1.30		.35

The assumed annual rate of hospitalization (all causes) was known to overstate the current frequency of hospitalization, thus introducing an additional margin for safety.

When the benefit was liberalized to include operations performed outside a hospital the rate for male employes was increased to $.40, and the rate for female employes increased proportionately. No change was made in the rates for wives and children. In practice the rate of $.40 per month per employe is charged for all employes in a group unless more than 11 per cent of the employes are females. If more than 11 per cent of the employes are females, the premium for employes is increased by the following proportions, and the same premium rate charged for all employes regardless of sex.

Per Cent of Insurance on Females	Additional Premium as Per Cent of Minimum Rate
11% to 21%	15%
21% to 31%	25%
31% to 41%	35%
41% to 51%	45%
51% to 61%	55%
61% to 71%	65%
71% to 81%	75%
81% to 91%	85%
91% to 100%	95%

Similar adjustments are made if the percentage of colored employes is abnormal.

If children are included a premium rate per family unit is used, based upon the assumption that the average family unit, averaging families with no children with families with one or more children, includes two children ("children" meaning only unmarried children between the ages of three months and eighteen years).

Thus, in this company, a policy will be issued insuring employes and their wives with a full scale of benefits at monthly rates of $.40 (or more) per employe and $1.30 per wife, or a

policy will be issued insuring employes, wives and children, at the same rate per employe, but at a rate of $2.00 per family unit, this rate applying to the family unit containing only a wife as well as to the family unit containing a wife and twelve children. The rates are reduced proportionately if the scale of benefits is reduced.

These group surgical benefits combined with hospitalization benefits have, for groups of employes and their dependents, gone a long way towards furnishing a solution to the problem of the large and unpredictable expense of medical care, and have done so without interfering in any way with the relationship between the patient and his physician. Any extension of group insurance to cover the costs of physicians' services other than for surgical procedures would be justified only if it could be offered on a basis which would permit of economical administration and upon a basis which would be generally acceptable to the medical profession. From the considerations previously set forth, it is obvious that either (1) the benefits must be restricted in their character, or (2) if the benefits are quite liberal, there must rest with the insurance company some direct control of the medical profession, or else the company must be prepared to spend a substantial percentage of its premium income to investigate and adjust claims. The one suggestion which has appealed to the author as feasible, from a purely financial point of view, is the restriction of medical care to services performed by doctors on a company selected panel. Since such a panel would necessarily be quite restricted, any such plan might well meet with opposition from the medical profession. The author is not recommending this idea, but calls attention to it since it is an essential characteristic of the community plans subsequently described. In these community plans, since all, or substantially all, of the physicians of the community may enter the plan, the same objection by the profession does not hold.

In the foregoing section of this article an attempt has been made to indicate the broader outlines of the problem and the extent to which insurance companies have sought to solve it. Under the impetus of the recent permissive legislation in a number of states various nonprofit organizations have organized or are organizing for the purpose of providing comprehensive medical services upon some basis of fixed annual cost. Both the fee-for-service basis and the annual capitation basis are used in remunerating physicians. These plans, being organized for the express purpose of insuring the cost of medical care, or providing medical care, are far less conservative in undertaking the risks involved in entering this new field than are the established insurance companies. These organizations have an important safeguard in the fact that they have contracts directly with the physicians who render the service and hence have, to some extent, both the coöperation of the physicians and control over them. The fact that these plans are more in the nature of community enterprises than in the nature of distant impersonal corporations, is doubtless an important protective factor. Despite all of these considerations, they are embarking upon hazardous and largely uncharted waters, and it would be well to watch carefully the few landmarks we know.

Once a plan of benefits has been formulated the very practical question is presented—What will these benefits cost? The answer naturally depends upon the basis and rate of compensation of the physician, and, if a fee-for-service basis, the frequency of conditions requiring insured medical service and the average number of visits per "illness." While these last two factors are not involved if the physician is paid on a capitation basis, they give the means of estimating the physician's probable income.

The interest in this subject during the past ten or fifteen years has resulted in a number of studies which have attempted to produce relevant statistics. Despite the enormous effort that has gone into these studies there appear to be very scant data upon which the actuary would rely in calculating the cost of such benefits. Fortunately there appear to be several independent approaches which furnish a means of determining reference points from which a guess may be essayed, for no calculation of the cost of insured medical benefits at the present time can be dignified as anything more than a guess. These approaches are as follows: first, an estimate may be made of the amount which individuals now pay for medical service; second, an estimate may be made of the cost of "adequate medical care" upon the basis of a given scale of fees; and third, an estimate may be made of the average charge per individual necessary to produce a given average income per physician.

Average Expenditures for Medical Care

Several studies of the average expenditures for medical care have been made within the past ten years. The most complete study is that of the Committee on the Costs of Medical Care made by Falk, Klem and Sinai, covering the experience of 8,639 white families in twelve consecutive months in the period from 1928 to 1931.[5] This study was made by means of a continuously supervised recording of the kind, frequency and duration of illness and the charges for incident medical care. The average charges for medical care were found to vary substantially by both income group and size of community. The smallness of the data when subdivided in this manner may have produced some unreliable results, but the consistency of these results is significant. The charges for services of physicians (other than oculists), excluding such charges merged in non-itemized charges of hospitals, clinics, laboratories, et cetera, as obtained from an unpublished tabulation derived from this study were as follows:

AVERAGE CHARGE PER PERSON PER ANNUM IN FAMILIES WITH SPECIFIED INCOMES

Size of Community	Under $1200	$1200 to 2000	$2000 to 3000	$3000 to 5000	$5000 to 10,000	$10,000 & over	All Incomes
Cities of 100,000 and over	7.23	7.29	9.81	14.41	20.71	44.64	13.21
Cities of 5,000 to 100,000	4.35	6.58	9.24	11.55	25.85	47.56	10.56
Towns of less than 5,000 and rural areas	4.50	6.04	8.11	10.96	16.93	28.83	7.25

The Metropolitan Life Insurance Company made a similar continuous study of medical expenses of all types (physicians' services, hospitals, nurses, medicines, etc.) for the six months period from January to July, 1929.[6] This study included 3,281 families in industrial centers. The average cost per person for all types of care during this six months period was $13.48. Very nearly half of the total recorded expenditures were for services of physicians (other than oculists), so that the above figure might fairly be taken as representative of the annual cost for physicians' services found by this survey. This compares with the over-all average of $9.43 for such services found by the Committee on the Costs of Medical Care.

A study of income of physicians, made by the Committee on the Costs of Medical Care, indicated the following average annual per capita payment during 1929 for services of physicians in private practice.[7]

Size of Community	Average Annual Expenditures for Services
Under 5,000	$ 3.31
5,000– 9,999	11.28
10,000– 24,999	9.59
25,000– 49,999	10.85
50,000– 99,999	12.43
100,000–499,999	16.25
500,000–999,999	15.89
1,000,000–and over	16.50
Total (Continental United States)	$ 8.88

A series of studies of the spending patterns of the United States population has recently been undertaken by the National Resources Committee, the United States Bureau of Labor Statistics and the Bureau of Home Economics. These studies were made by a census procedure whereby an attempt was made to obtain at one time a comprehensive record of the expenditures, for the preceding twelve months period, of the families included in the controlled samples. This procedure must sound strange to the actuary who has spent considerable time with the problems involved in the correction of errors in population statistics resulting from intentional and unintentional misstatements of such a simple bit of information as age. With respect to the reliability of the resulting data the Bureau of Labor Statistics states:

> An investigation of family income and consumption by means of schedules filled after the end of the report year is confronted with questions concerning the degree of accuracy with which families may be expected to remember details of expenditures made over a period of twelve months. It is admittedly impossible to obtain by the schedule method precise records of expenditures for each item included in family living. It is believed, however, that accuracy sufficient for the purposes of generalization can be achieved. One means toward this end followed by the Study of Consumer Purchases was the use of highly detailed schedule forms which served to remind families of the wide variety of items for which they might have incurred expenditures during the year. Such schedules, filled through painstaking interviews, provided data that in the great majority of cases undoubtedly represented closely the spending patterns of the families interviewed.

Despite the serious question as to the reliability of such a method for the purpose of indicating the exact amount expended for any specific item, there are shown below, for what they may be worth, figures derived from this study with reference to the per capita expenditures for services of physicians in New York City.[8] Considering the difference in the dates of the studies, there is a surprising correspondence between these figures and those for cities of 100,000 and over produced by the study of the Committee on the Costs of Medical Care. It is difficult to reconcile this close agreement with the indications of substantial decline in physicians' incomes during the interval between the two studies.

AVERAGE ANNUAL PER CAPITA EXPENDITURES FOR PHYSICIANS' SERVICES, 1935-1936

(Non-Relief Native White Families in New York City)

Income Level	General Practitioner	Specialist	All Physicians
$ 500–$ 999	$ 1.99	$ .15	$ 2.14
1,000– 1,499	4.51	1.24	5.75
1,500– 1,999	6.73	2.17	8.90
2,000– 2,499	8.89	2.54	11.43
2,500– 2,999	8.68	3.12	11.80
3,000– 3,499	9.12	6.95	16.07
3,500– 3,999	10.48	5.77	16.25
4,000– 4,999	13.53	4.33	17.86
5,000– 7,499	15.73	9.94	25.67
7,500– 9,999	26.75	14.71	41.46
10,000–and over	42.07	21.03	63.10

From such data as is available it appears probable that the average per capita expenditure for physicians' services is less than $10 per year, the average increasing substantially with increase in income level, and to a lesser degree with increase in size of community. While the premium for any plan of comprehensive medical service would properly be in excess of the present average expenditure it is probable that if the difference is too great, for the same economic and community group, the benefit would be very difficult to sell and the tendency towards adverse selection would be seriously increased.

Estimates of the Cost of "Adequate" Medical Care

One of the projects of the Committee on the Costs of Medical Care was an attempt to give concrete, statistical meaning to the term "adequate" medical care.[9] In this study good medical care is defined as "the kind of medicine practiced and taught by the recognized leaders of the medical profession at a given time or period of social, cultural, and professional development in a community or population group." There is no finality in this definition, it is a dynamic concept, and it will be noted that while on the one hand "good medical care" at a given time and place is something more than the average person is receiving, since it is the kind of medicine practiced by the leaders of the profession, it may be less than "good medical care" at a later time or in another place.

A standard table of sickness rates was developed by Lee and Jones from a comprehensive review of available sickness statistics. For all acute conditions, their expectancy rates describe the number of attacks to be expected during a year in an average population group. For chronic diseases, the rates describe the number of persons who are affected during a year.

Lee and Jones grouped diseases and defects in nineteen broad categories. In each category there were selected certain "typical diseases" as illustrative of service requirements. The average amount of service for typical diseases in each such category was assumed to hold for all diseases in the category. Estimates of medical service in the prevention, diagnosis, and treatment of diseases and of physical and mental defects were obtained by Lee and Jones from physicians in general practice and in special practice in several parts of the United States.

Two estimates of the cost of adequate medical care have been published, using in each case the standards of adequacy set up by Lee and Jones. The earlier study by Bradbury accepted the Lee and Jones estimates of the incidence of illness requiring medical service and computed costs based upon the schedule of minimum fees printed in the 1933-1934 "Blue Book" of the Chicago Medical Society.[10] Upon this fee schedule the cost of "adequate medical care," including x-ray and pathology but excluding mental and nervous conditions and the cost of refractions, was estimated to be $37.50 per person per annum. The later study by the Bureau of Medical Economics of the American Medical Association[11] substituted figures as to incidence of illness compiled by the United States Public Health Service,[12] and utilized an unpublished compilation by the Bureau of Medical Economics of median minimum fees based upon the fee schedules of 559 county medical societies. This calculation produced a cost

for medical care, again exclusive of mental and nervous conditions and cost of refractions, of $15.83 per person per annum. No provision was made in this latter computation for the cost of x-ray and pathology. The resulting estimated cost of medical care is comparable with an estimate for similar services of $26.33 per person per annum in the Bradbury study.

The size of the Bradbury estimate raises serious question as to the adequacy of our existing facilities to supply such service and the ability of our present economy to pay for it. In this connection attention should be called to the comments of the Committee on the Costs of Medical Care:

> If the people of the United States were receiving the medical care which they need and which the dictates of medical art and science warrant, the army of medical practitioners would have to be larger than it is at present and existing medical agencies probably could not supply services equal in quality or volume to those which the standards [of good medical care] prescribed, and the people probably would not, and could not afford to, buy them if they could be furnished.[13]

ESTIMATES OF THE COST OF "ADEQUATE" MEDICAL CARE

(Excluding the cost of treatment of nervous and mental conditions and the cost of refractions)

Medical Care in Treatment of the Following Diseases and Conditions (Excl. of operations, laboratory and x-ray)	Average Annual Cost Per Person	
	Bureau of Medical Economics Estimate	Bradbury Estimate
Communicable diseases		
Syphilis and gonorrhea	$ .06	$ 2.10
All others	1.19	1.83
General diseases	.70	.63
Diseases of eye and ear	1.59	1.23
Diseases of circulatory system	1.19	.83
Diseases of respiratory system	2.78	6.50
Diseases of digestive system	.47	1.32
Diseases of skin and cellular tissue	.53	.27
Diseases of muscles, bones and joints	—	.26
Diseases of kidney and annexa	.49	.51
Non-venereal diseases of the G.U system	.37	.29
The puerperal state	1.26	1.32
Malformation and early infancy	.06	—
All accidents	.35	.68
All other conditions	.69	—
	$11.73	$17.77
Operations	4.10	8.56
	$15.83	$26.33
Laboratory service		5.36
X-ray service		5.81
		$37.50

The lower figure brought forth by the Bureau of Medical Economics is based upon the same standards of medical care as those used by Bradbury, and there are few substantial differences in the frequencies of illness assumed in the two studies. The results of the two studies may be brought into reasonable agreement if allowance is made for the higher incidence of venereal diseases, the greater frequency of treated diseases of the respiratory system, the higher per illness cost for treating diseases of the digestive system, and the much higher average cost per operation assumed in the Bradbury study. It should be noted that the frequency of venereal diseases included in the Bureau study is derived from data based upon voluntary statements, and hence would tend to be considerably understated. The Bureau study also made no provision for the cost of treating common colds, despite the fact that the low incidence of colds (.107 per person per annum) included in the morbidity data upon which the calculation was based would indicate that only colds of more than average severity were included in that data. A comparison of the estimates of the cost of services for the different disease categories is given in the accompanying table.

It appears from both of the foregoing studies that "adequate" medical care provided upon a fee-for-service basis at customary "minimum" fees (probably more correctly termed standard fees) would cost several times as much as the average person now pays for medical care. This large discrepancy is due to the fact that "adequate" medical care requires more service than is now rendered to the average person, and to the fact that the average collected fees for various units of service are less than the so-called "minimum" fees.

Average Income of Physicians

The evidence as to present average incomes of physicians is not very satisfactory. Studies have been made by the American Medical Association[14] and the Committee on the Costs of Medical Care[7] of the average income of physicians during the period from 1928 to 1930. These studies were based, in most instances, upon voluntary statements by physicians concerning their incomes, although in the study by the Committee on the Costs of Medical Care recourse was also had to income tax returns for 1929. As

might be expected, there is evidence in these returns of a tendency for the average income derived from the data to decrease with an increase in the percentage of questionnaires returned.

The American Medical Association study indicated incomes of physicians in private practice during 1928 as follows:

Type of Practitioner	Number in Sample	Average		Median	
		Gross	Net	Gross	Net
All practitioners.....	5,475	$10,440	$6,499	$8,090	$4,938
General practitioners	3,470	8,078	4,887	6,839	4,138
Specialists.....	2,005	14,527	8,876	11,575	7,072

The study made by the Committee on the Costs of Medical Care indicated the following incomes during 1929 for physicians in private practice.

Type of Practitioner	Number in Sample	Average		Median	
		Gross	Net	Gross	Net
All practitioners.....	6,989	$ 9,461	$5,700	$7,026	$4,100
General practitioners	3,965	6,421	3,900	5,245	2,900
Partial Specialists...	1,444	9,995	6,100	8,292	5,000
Complete Specialists.	1,580	16,304	10,000	12,239	7,500

As would naturally be supposed there was considerable variation in the indicated incomes by size of community, although the median incomes vary less than the average incomes.

No statistics are needed to know that the incomes of physicians have decreased substantially since the period of the above studies. Preliminary reports of a study by the National Bureau of Economic Research indicate that the average net incomes of physicians in private practice, including both general practioners and specialists, were in the neighborhood of $3,500 to $4,000 during the period from 1934 to 1936. It is frequently assumed that the net income represents approximately 60 per cent of the gross income, hence it may be assumed that the more recent statistics indicate an average gross income, for physicians in private practice, in the neighborhood of $6,500.

The ratio of physicians to population varies considerably from one section of the country to another. However, for practically all sections the ratio of physicians to population has shown a continuous decline during the current century. The number of physicians per 1,000 persons in the United States is given by the Committee on the Costs of Medical Care as 1.73 in 1900, 1.64 in 1910, 1.37 in 1920 and 1.26 in 1929.[13] These figures include in the number of physicians those physicians who are retired and those employed on salaries by governmental agencies, hospitals and teaching institutions. In 1929 the ratio of independent private practitioners to the population was practically one per 1,000. On the other hand, it should be noted that the population figures used above include persons in institutions and those on relief. All things considered, it would seem conservative to assume, in testing the adequacy of any rates proposed for a plan of insured benefits, a ratio in the neighborhood of one physician to 700 patients.

Several nonprofit corporations have organized, or are in the process of organization, under the provisions of the 1939 amendment of the New York insurance law permitting the formation of medical expense indemnity corporations. The New York insurance law states that "Medical expense indemnity shall consist of reimbursement for medical care provided through duly licensed physicians, for nursing service and of furnishing necessary appliances, drugs, medicines and supplies." In practice the corporations which have been organized restrict the indemnity to reimbursement for care provided by physicians. An outline of the proposed plans of two of these corporations being organized in New York City is given below. These plans are not presented as models of perfection, nor as horrible examples. It is to be hoped that a critical examination of their structure by members of this body may serve to throw light on the difficulties which may be encountered by these and similar organizations.

It should be pointed out that neither of these organizations has been quite adventurous enough to follow the pattern of the hospital service associations to the extent of proposing to offer a family coverage contract at a rate which is not in proportion, when compared with the rate for individual coverage contracts, to the increased risk involved. However, both have followed the precedent of these associations in ignoring in their premium rates the difference in incidence of volume and cost of medical service by age, sex, and marital status. In both cases an average rate is determined upon the assumption that the insured group will be no worse than a representative cross section of the population. Sales meth-

ods and underwriting procedure may well make the insured group better or worse than such a cross section.

It is obvious that a conservative estimate of the cost of medical care under an insured plan will be greater than the amount that the average person is now paying for medical care. At the same time it does not appear probable that the average person would be willing to pay the price indicated above for "adequate" medical care. It appears reasonable to assume that an insurance plan with proper safe-guards will experience a demand for service in excess of that found by the Committee on the Costs of Medical Care, i.e., an average of 2.39 physician's visits per person per year,[5] and less than that indicated by Lee and Jones as necessary for "adequate" medical care, i.e., 6.6 visits per person per year.[9]

One of the groups described below is organized as a consumers' coöperative, and while its policies are, as must necessarily be the case in any such group, the result of conference and compromise between lay people and medical people, these policies are largely the product of a lay approach. As opposed to this approach, the second plan described is sponsored by a group of physicians and its policies are largely the product of a medical approach.

In the consumers' coöperative group emphasis is placed on preventive and early therapeutic care. Medical care to be provided includes

(a) Initial and periodic physical examinations
(b) Service of general practitioner and specialists, including office, home and hospital calls, except for
  (1) pre-existing conditions
  (2) treatment of pregnancies commencing within 11 months of entrance
  (3) conditions compensable by government or under law
  (4) eye refractions
  (5) care in cases which become institutionalized
  (6) treatment of functional nervous or mental conditions
  (7) drug and alcohol addiction
(c) Laboratory and x-ray service
(d) Physiotherapy.

The general practitioner and pediatrician (who will, if desired, serve in place of the general practioner for children up to age fifteen) will be remunerated on a capitation basis, while specialists will be remunerated on a fee-for-service basis combined with a unit disbursement arrangement. Laboratory work will be handled by a commercial laboratory.

Obstetrical care is subject to an additional charge of $25, while the subscriber must pay one-third of the standard fee for x-ray service, but not in excess of $10 per year. A charge of $1 is made for the first home call by the general practitioner in treatment of each illness. Except for these extra charges, and the exclusions outlined above, the medical care to be provided is unlimited.

The premiums for this plan were computed upon the following assumptions:

(1) That the average general practitioner could handle a panel of about 1,400 patients if he handled no obstetrical or pediatric work, and should receive for such full time service, about $7,000 per year.

(2) That the average pediatrician could handle a panel of about 880 children and should receive an income for such full time service of about $8,000 per year.

(3) That the average specialist collects about 75 per cent of the standard, or prevailing fees, for the service which he renders, and that the volume of service required would be that indicated by the Lee-Jones study.

(4) That the average birth rate among insured subscribers would be 18 per 1,000 (as compared with a population birth rate of 14.26 per 1,000 in New York City during 1938), and that the cost per pregnancy is $100, of which $15 is defrayed by the additional charge. (The other $10 is assigned to cover some of the extra cost of pediatric service for children during the first year of life.)

(5) That an annual frequency of 140 x-ray procedures per 1,000 subscribers may be expected, and that the average standard fee per x-ray procedure would be $16.00, of which one-third will be paid by the patient and the balance (41.7 per cent) necessary to produce a payment of 75 per cent of standard fees, paid by the company. It should be noted that the frequency of x-ray procedures is lower than that assumed by Lee and Jones (171 per 1,000). This assumption is reminiscent of the following statement by Watson.

I have had instances repeatedly wherein a moderate reduction in the rate of sickness benefit was followed by very substantial reduction in the quantity of claims, and I have consequently become accustomed to base my estimates of the practical value of reforms upon the expectation that a reduction in the rate of benefit, in the cases in which malingering is suspected, will be accompanied by a decline in the number and duration of the claims.[15]

(6) That 1,300 laboratory procedures (exclusive of those done without cost to the company, by general practitioners, or the public health department) will be required annually per 1,000 subscribers, and that this service can be obtained from a commercial laboratory at $.27 per procedure.

These assumptions result in an estimated net annual cost as follows:

	Estimated Annual Per Capita Cost
General care (including pediatrics)	$6.00
Specialist care (other than obstetrics and x-ray diagnosis)	6.00
Obstetrics	1.53
X-ray diagnosis	1.00
Laboratory work	.35
Net Annual Premium	$14.88
Loading	3.12
Gross Annual Premium	$18.00

(Based upon estimated annual costs of $5.00 per adult and $9.10 per child, weighted 75 per cent and 25 per cent respectively.)

The uncertainty of these assumptions and the resulting estimated cost, both in the aggregate and for the various types of service, is illustrated by the fact that, after determination of the premium in the foregoing manner, provision was made to increase the annual capitation fee for general practitioners to $6.50 and for pediatricians to $10.35, reducing the provision for specialists accordingly. It will be recalled that the specialists are to be compensated under a unit disbursement plan.

Special attention is called to the fact that the uninsurable nature of early therapeutic care is recognized by the arrangement to remunerate general practitioners and pediatricians upon a capitation fee basis. The important question remains as to whether at $6.50 per year for adults and $10.35 per year per child, this plan will sufficiently compensate general practitioners and pediatricians so that physicians of proper qualifications will be attracted to the plan and be satisfied by it in operation. The evidence on both sides of this question is, to the writer's mind, inconclusive.

The proposed benefits of the second organization are in the nature of indemnification for the expense of medical service furnished by participating physicians in treatment of serious illnesses and injuries. This plan, in contrast to the one just described, does not include provision for periodic health examinations. A stipulated deductible sum with respect to each illness, varying according to the subscriber's economic status, must be paid by the subscriber to the physician before any benefits accrue. The maximum amount of indemnity which may be provided in any one year is $500, and within this maximum various amount limitations are applied to the different types of service. The rates, and limits, of indemnity are indicated by the accompanying table.

Service of	Maximum Rate of Indemnity	Limit of Indemnity During any 12 Consecutive Months
General practitioner		$300
(a) Office visit	$2.00 per visit	
(b) Home visit—daytime	3.00 per visit	
(c) Home visit—night (if service is required between 12 P.M. and 7 A.M.)	5.00 per visit	
Specialist	In accordance with schedule of fees consistent with New York State Workmen's Compensation fee schedule.	100
Surgeon		300
Surgical operation, including after care		
Pathologist		50
Radiologist		
(a) Diagnostic x-ray		100
(b) X-ray and radium therapy		300
Anesthetist		75

The exclusions under this plan are substantially the same as those in the one just described.

In determining the premium rate for this organization it was assumed,

(1) That there would be an average of 2.5 visits to general practitioners per year per person, exclusive of health examinations and obstetrical care, and that a deductible sum of $10 per illness would eliminate from the scope of the insurance one-half of the visits to the general practitioner,

(2) That the average fee per visit to general practitioners under the fee schedule adopted would be $2.50,

(3) That there would be an average of .5 visits per year per person to specialists, exclusive of

visits incident to surgical care, and exclusive of x-ray service,

(4) That the average fee per visit to specialists, after deduction of amounts paid under the deductible sum provision, would be $5,

(5) That the average annual frequency of surgical procedures would be 6.5 per 100 and the average fee per operation, in excess of any amount paid under the deductible sum provision, would be $50,

(6) That the average annual frequency of births would be 1.5 per 100 and that the average fee, in excess of amounts paid under the deductible sum provision, would be $65,

(7) That the average annual frequency of services of an anesthetist would be 5 per 100 and that the average fee would be $10,

(8) That x-ray and pathology service would cost $1.50 per year per person.

The following tabulation summarizes the calculation of the net premium.

General practitioner	
Average of 2.5 visits per year, of which one-half are excluded, @ $2.50 per visit	$ 3.13
Specialist	
Average of .5 visits per year @ $5.00 per visit	2.50
Operations	
Frequency of .065 per year @ $50 per operation	3.25
Obstetrical Care	
Frequency of .015 per year @ $65 per case	.98
Anesthetist	
Frequency of .05 @ $10 per case	.50
X-ray and pathology	1.50
Net premium	$11.86

To this net premium was added a loading of 25 per cent, producing a gross annual premium of $15.00.

The direct payment to the physician under the $10 deductible sum provision was assumed to average $6 per year per person. It will be seen that the average cost of medical care produced by this calculation is substantially in excess of present expenditures.

In an attempt to carry into this plan the traditional gradation of charges for medical care in accordance with economic status it is proposed to make provision for different premiums for persons of different income and family responsibilities. The classification adopted is shown in the accompanying table.

The premium rates for these classes were graded empirically, adopting the above rate of $15 a year for Class A, $12.60 for Class B, $10.80 for Class C and $9.00 for Class D. The

ECONOMIC STATUS—INCOME PER MONTH

Class	Married Persons and Members of Their Families	Single Persons
A	over $175	over $125
B	$140–$175	$100–$125
C	$100–$140	$ 75–$100
D	under $100	under $ 75

deductible sum was also graded from $10 for Classes A and B to $7.50 for Class C and $5.00 for Class D. The payments to physicians will be on a unit disbursement plan, the funds for each class being kept separate for this purpose. It is estimated that if the foregoing assumptions as to average amount of medical care are realized these premiums will permit payment of 100 per cent of the standard schedule fees for services to the Class A subscribers, 80 per cent of such fees for services to the Class B subscribers, 60 per cent for services to the Class C subscribers and 40 per cent for services to the Class D subscribers. Obviously different assumptions as to the average amount of medical care would change these ratios.

If the selection of subscribers is such as to produce a representative cross section of the population, and if the medical service required by the subscribers is such as to permit an average of 700 subscribers per full time physician, then these rates are apparently sufficient to provide an average gross annual income per physician in the neighborhood of $8,000, or an average net income in the neighborhood of $5,000.

The difficulty of determining the economic status of the individual, for purposes of correct determination of his class, and of making adjustments as an individual's status changes, are obvious. Some of these difficulties are minimized when the enrollment is conducted on a group basis. The claims administration procedure may also be utilized to pick up some of the unavoidable misstatements and changes in status. Only experience will tell whether the substantial difficulties which remain can be controlled by other means.

As previously stated, sound sales and underwriting procedures are vital to the success of these organizations. Both of the above organizations contemplate enrollment of subscribers under substantially group underwriting rules, with payroll deduction or its equivalent, although the

contracts to be issued will be individual contracts. However, both organizations contemplate enrollment of individual subscribers, at somewhat higher premiums, subject to satisfactory medical examination. Under the group enrollment procedure an employe might apply for coverage for himself, his wife and children, the same rate being charged for each individual covered.

While it is the writer's desire to make this article completely objective, he feels that the following generalizations with reference to the insurance of the expense of medical service are warranted:

1. Not all types of physicians' services meet the requirement, for an insurable hazard, that the happening of the event must not be subject to the control of the insured individual. The services which most nearly meet this criterion are surgical procedures and treatment of injuries received in accidents. The services which fail most completely to meet this criterion are health examinations, obstetrical care, the first few visits of a physician in treatment of an illness, and x-ray service.

2. If the physician is remunerated on a capitation fee basis, the financial effect upon the "insurer" of the non-insurable nature of early visits by physicians is eliminated. In this situation, however, the individual physician must bear the risk of providing an unpredictable amount of benefit for a fixed annual price, and hence becomes the real insurer of these services.

3. While not an insurable hazard, periodic health examinations may, in view of their predictable nature, constitute a type of service which can be incorporated in a plan of insurance without endangering the financial stability of the insurer, if proper provision is made for the cost of such examinations.

4. Obstetrical care can be safely included in a plan of insurance only if the method of enrollment of subscribers is such as to avoid, or minimize, self-selection for the purpose of taking advantage of such benefits. If such self-selection is substantially avoided, obstetrical care, although not an insurable hazard, also constitutes a type of service which can appropriately be added to a plan of insurance of medical expense.

5. Any plan which attempts to furnish comprehensive medical service must offer benefits which are, to a greater or lesser degree, not insurable risks, and hence, to prevent undue abuse of the plan, must rely upon some method of supervision of the physicians providing the service and upon the right of cancellation of individual subscribers' contracts.

6. There is an almost complete lack of statistics satisfactory for the precise determination of the cost of insured medical services. It seems highly probable that under any insured plan the rate of demand for services will be increased, and hence, ignoring administrative expenses, either the average cost of service to the public must be greater than at present or the rate of remuneration to physicians per unit of service must be less. It also seems reasonable to assume that the average cost should be less than that indicated by the existing estimates of the cost of "adequate" medical care, unless there is a substantial increase in the ratio of physicians to population.

7. A sound basis of selection of lives to be insured is fundamental to the success of any plan undertaking to insure the expense of medical services. Employed individuals enrolled on a group basis, with minimum participation requirements, are undoubtedly the best risks. The enrollment of dependents of employed individuals with similar participation requirements, and the enrollment of individuals with conservative medical examination requirements, may furnish a sound basis of selection.

REGISTRATION FEES

At a recent meeting of the Minnesota State Board of Medical Examiners Dr. Max W. Alberts presented a request from Medical Reserve officers, who had been called into active service, that they be exempt from paying the annual registration fee while on duty. The board would have liked to accommodate these men, but it realized that it had no power to waive the fee since it is stipulated by law. Should the law be changed, the board would be compelled to curtail its legal activity in prosecuting quacks because the present income is scarcely enough to conduct its present active program. The board hoped that the local county medical societies would find a way to assume the registration fees for its members who are away in Army service.

Minneapolis Man Pleads Guilty to Performing Abortion on Wife

Re: State of Minnesota vs. Melchior Erick Arvidson.

On March 15, 1941, Judge W. W. Bardwell of the District Court of Hennepin County, sentenced Melchior Erick Arvidson, thirty-seven years of age, to a term of not to exceed four years in the State Reformatory at St. Cloud, and then stayed the execution of the sentence, placing the defendant on probation for a period of two years. Arvidson was arrested by Minneapolis police officers on January 26, 1941, in his home at 5621 31st Avenue South, Minneapolis. According to Arvidson's statement to the Police Department, he is a WPA worker and the father of three children ranging in age from nine months to six years. His wife was again pregnant and had told her husband that unless she was able to terminate her present pregnancy, she would commit suicide. The husband stated that his wife purchased a catheter which he attempted to insert into the uterus. He then forced air into the catheter with Mrs. Arvidson dying almost immediately. The cause of death was given as an air embolism from attempted induced abortion. Arvidson was indicted by the grand jury of Hennepin County on February 4, 1941, charged with the crime of abortion. On being arraigned in Court, he entered a plea of not guilty and bail was fixed at $3,000.00. However, on February 10, 1941, Arvidson withdrew his plea of not guilty and entered a plea of guilty, the matter being referred to the Probation Officer of Hennepin County for an investigation.

Arvidson holds no license to practice any form of healing in the State of Minnesota, and neither has he any education in any of the healing arts. There was no evidence to indicate that Arvidson had been engaged in any other similar illegal activities, although he did state that his wife had previously aborted herself on several occasions with elm bark.

Minnesota Supreme Court Upholds Conviction of Minneapolis Physician for First Degree Manslaughter

Re: State of Minnesota vs. R. J. C. Brown, M.B.

On March 7, 1941, the Supreme Court of Minnesota affirmed the conviction of Richard J. C. Brown, M.B., Negro physician of Minneapolis, who was convicted of manslaughter in the first degree on November 22, 1939, by a Hennepin County District Court jury. Brown has been taken to the State Prison at Stillwater to commence his sentence of not less than five and not more than twenty years at hard labor.

Brown was arrested on August 16, 1939, by the Minneapolis Police Department following a complaint being signed against him by the father of a twenty-two-year-old girl upon whom it was claimed that Brown had performed a criminal abortion. The complaint alleged that the abortion was performed on July 31, 1939, the girl dying on August 23, 1939, at the Minneapolis General Hospital. At the trial, Brown did not take the witness stand in his own behalf.

According to the records of the Minnesota State Board of Medical Examiners, Brown was born at Lincoln, Nebraska, January 17, 1893, and graduated from the University of Minnesota on June 17, 1920. He was licensed to practice medicine in Minnesota the same year. The records at the University of Minnesota disclose that Brown never completed his internship and the degree of Doctor of Medicine was never conferred upon him. Brown's license to practice medicine in Minnesota was revoked by the Minnesota State Board of Medical Examiners on February 9, 1940, following his conviction.

MISCELLANEOUS

Chest X-ray Methods

Experimenters have worked to devise a means of making chest x-rays of groups of people, economically and at a rapid rate. Last year approximately 490,000 students received special service which, in most cases, included an x-ray examination. Industrial groups are demanding a similar service. Mobilization for military training has further focused attention on mass methods of x-ray examination. S. Reid Warren, Jr., of the Moore School X-ray Laboratory here presents brief comments of six methods now in use. Estimates of costs and weights are averages from which particular data may differ. The choice of methods depends, of course, on the particular task to be done.

Stereoscopic 14 by 17 inch Films

This is the best single method of chest x-ray examination. It requires expensive ($4,000-$5,000), bulky (1,000 pounds) equipment which must be permanently installed in conjunction with an adequate system to supply electric power to it (230 volts, 35-150 amperes alternating current). Exposure times from 1/30 second to 1/10 second are generally used. A specially equipped darkroom is required to process the films. Two films (unexposed film—$1.50) are required for each examination. It is difficult to make exposures, process the films, and examine them fast enough to use this excellent method for mass surveys. The excellence of this method is the result of (1) high contrast within the diagnostic area of each roentgenogram, (2) small unsharpness or blurring of shadow borders, (3) convenient size for direct viewing, and (4) stereoscopic perception (Fig. 1).

Single 14 by 17 inch Films

The same kind of x-ray generating apparatus is used for producing stereoscopic and single chest roentgenograms. The auxiliary equipment for making single films is less complicated and bulky. Apparatus has been constructed which can be carried in a truck and assembled to examine groups. One film (unexposed—$0.75) is required for each examination. Advantages of this method are (1) high contrast, (2) small unsharpness of shadow borders, and (3) convenient size for viewing (Fig. 1).

Rolls of Paper 14 by 17 inch

Rolls of paper 14 inches wide and about 150 feet long coated on one side with a photographic emulsion are used for this method which was devised specifically for surveys. A roll of paper is mounted within a light-tight mechanism which is arranged so that, after the first roentgenogram is made near one end, the paper can be moved about 18 inches in preparation for the second exposure. After 100 exposures are made, the roll is removed and processed in special equipment. The roentgenograms are viewed by reflected light in a viewing device in which the roll of paper can be mounted. The x-ray apparatus and technic for paper are practically equivalent to those used for 14 by 17 inch film, though slightly more exposure is required for paper. The contrast in paper is less than in film although the diagnostic value appears not to be seriously com-

promised by this deficiency. Apparatus is transportable in a truck, rate of exposure is high (100 per hour), and examination of the roentgenogram is quick and convenient. The company which has developed this method supplies all apparatus, and delivers completed roentgenograms to the physician for $0.75 to $1.00 per patient (Fig. 2).

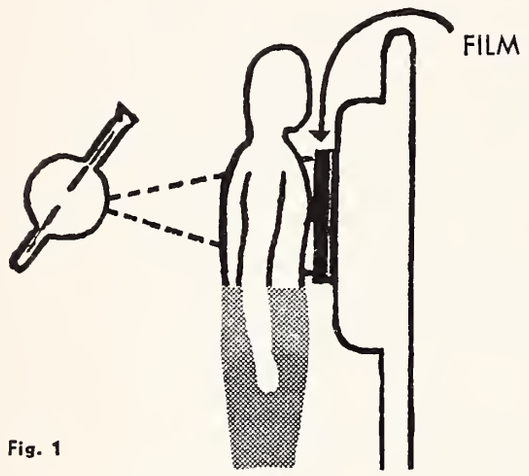

Fig. 1

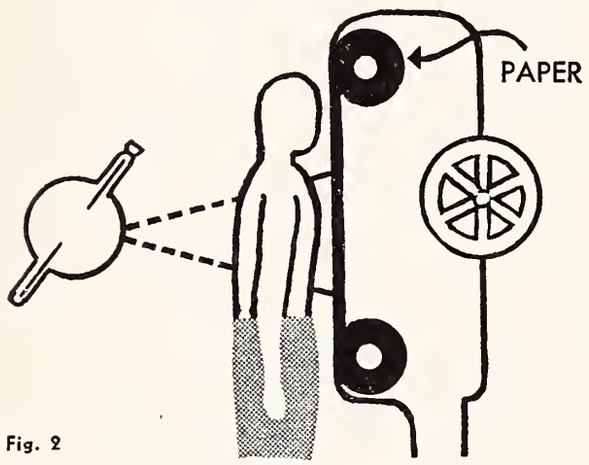

Fig. 2

Photofluorograms

In these methods, *x-rays* pass from the tube through the patient to a (14 by 17 inch) fluorescent screen which is thus caused to emit *light*. A photographic camera is focused upon the fluorescent screen in order to record the pattern of areas of varying brightness of *light* produced on the screen by *x-rays*. The screen, lens, and photographic film must be as fast as possible in order not to require excessive x-ray exposure. High-voltage generating equipment like that used for 14 by 17 inch film is required for photofluorography. Using screen and cameras now available, the unsharpness or blurring of shadow borders is greater in photofluorograms than in 14 by 17 inch roentgenograms.

The lens used to make 4 by 5 inch photofluorograms is expensive ($1,000). The 4 by 5 inch film is large enough to view without magnification. These films can be processed more conveniently than 14 by 17 inch film; the cost (one processed film, $0.06) and filing space are far less for the smaller (4" x 5") film. Four inch film in rolls is not available.

The lens generally used to make 35 mm. photofluorograms is an f:1.5 lens of the type used in miniature cameras. The 35 mm. photofluorogram must be enlarged for clear viewing. Rolls of film can be exposed and processed by means of easily available photographic equipment; the cost (for each processed film, $0.02) of film for each exposure is of course very small.

These methods are being studied in order to find means of overcoming the low contrast and gross unsharpness which are their chief disadvantages (Fig. 3).

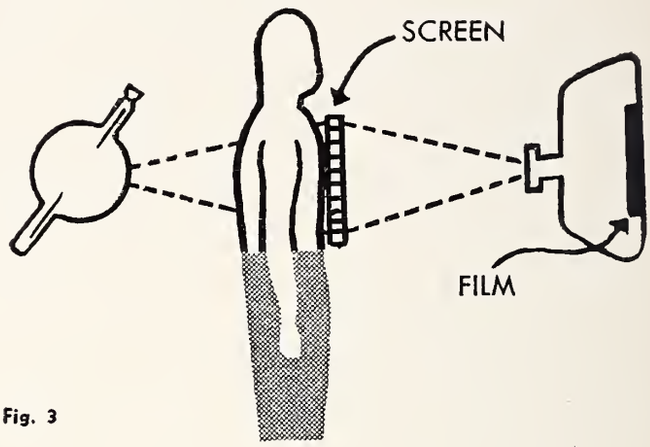

Fig. 3

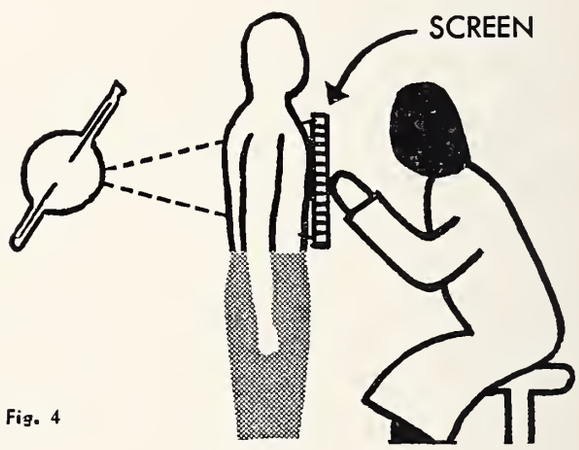

Fig. 4

Fluoroscopy

Apparatus for fluoroscopy is relatively inexpensive ($800) and it requires a relatively low power input (10 volts, 10 amperes alternating current). The physician examines the fluorescent image of the chest in a darkened room and records his opinion. Thus there is no permanent record which can be reëxamined by others. The contrast and sharpness of the fluoroscopic image are greatly inferior to those of a good 14 inch by 17 inch roentgenogram. The physician is subjected to scattered x-rays during the examination. This may be dangerous in a mass survey (Fig. 4).

No x-ray survey method is an adequate substitute for a complete x-ray examination of the chest. The purpose of a survey is to segregate as accurately as possible those subjects whose chests are normal and those subjects who should be referred to a roentgenologist for a complete examination because of suspicious shadows seen by the physician who conducts the survey.—Tuberculosis Abstracts, April, 1941.

OF GENERAL INTEREST

A daughter, Harriet, was born to Dr. and Mrs. Alexander Blumstein of Minneapolis, January 13.

* * *

Dr. and Mrs. John A. Haugen of Minneapolis are the parents of a daughter, Martha Caroline, born February 14.

* * *

Dr. F. A. Willius and T. E. Keys of Rochester are the authors of a book, "Cardiac Classics," which has just been released by the publishers.

* * *

Dr. Theodore F. Hammermeister of New Ulm has fully recovered after an illness of several months, and has resumed his practice in medicine and surgery.

* * *

Dr. and Mrs. George F. Engstrom of Belgrade returned in March after a two-months' vacation in California.

* * *

Dr. Percy C. Johnson, who has been assistant physician at the Tyler Clinic in Tyler, has entered into partnership with Dr. A. L. Vadheim in the clinic.

Dr. James B. Carey of Minneapolis has taken on editing duties in addition to his medical practice. He is editor of the *Nicollet Clinic Bulletin,* a quarterly publication. The first issue of the second volume is scheduled to appear this month.

* * *

Dr. Edward C. Maeder of Minneapolis will give the final lecture in a marriage forum being held by the Minneapolis Seton Guild. He will talk on "Biology of Marriage," at the Seton Guild, April 7.

* * *

Dr. Ernest S. Mariette presented a review of twenty-five years of service of the Glen Lake Sanatorium in a recent issue of the *Bulletin of the Hennepin County Medical Society.*

* * *

Dr. Waltman Walters of Rochester delivered the seventeenth Lewis Linn McArthur Lecture of the Frank Billings Foundation of the Institute of Medicine in Chicago, March 28. His subject was "Pathologic Physiology of the Common Bile Duct."

* * *

Officers of the Minnesota State Board of Health were reëlected at a recent meeting. Dr. E. S. Platou of Minneapolis is president; Dr. T. B. Magath of Rochester, vice president; and Dr. A. J. Chesley, secretary and executive officer.

* * *

Dr. Ralph V. Platou, who is completing work for his Ph.D. in pediatrics at the University of Minnesota Medical School, is to become associated in practice with his brother, Dr. Erling S. Platou, 953 Medical Arts Building, Minneapolis.

* * *

Dr. John O'Hanlon of Norwood has taken over the practice of Dr. Arthur Neumaier of Lindstrom, who has been called to active duty with the United States Army. Dr. Neumaier has been assigned to Carlisle Barracks in Pennsylvania.

* * *

Dr. Leo G. Rigler and Dr. John R. Paine of the University of Minnesota Medical School will go to Chicago, April 10, to present a paper, "Clinical and Roentgenological Manifestations of Acute Abdominal Disorders," before the Chicago Roentgen Ray Society.

* * *

The annual Russell D. Carman lecture, presented under the auspices of the St. Louis (Missouri) Medical Society, was given March 25 by Dr. Byrl R. Kirklin of Rochester. His subject was "Cancer of the Gastro-intestinal Tract: Its Early Manifestations."

* * *

Dr. Irvine McQuarrie, head of the department of pediatrics at the University of Minnesota Medical School, was in Chicago, March 27, to attend a meeting of the Council on Foods and Nutrition of the American Medical Association, of which he is a member.

* * *

En route to Muncie, Indiana, where he was to begin his duties as a staff physician at Muncie Clinic, Dr. J. J. Westra of Owatonna was injured in an automobile accident, March 13. He suffered a fractured leg and jaw, and was taken to a Charles City, Iowa, hospital for treatment.

Dr. E. J. Schmitz, a graduate of the University of Minnesota Medical School, has taken over the surgery practice of Dr. M. C. Kern at Freeport. Dr. Kern is with the 217th coast artillery, United States Army, in California. Dr. Schmitz recently completed his internship at the Northwestern Hospital in Minneapolis.

* * *

Dr. J. A. Williams of Minneapolis has opened offices in Hibbing for the general practice of medicine and surgery. He is a graduate of the University of Minnesota Medical School, and served internships at the Swedish Hospital in Minneapolis and at St. Mary's Hospital in Duluth. * * *

Naval Reserve officers in Minnesota who have been recommended and approved for promotion to the grade of commander in the volunteer reserve of the medical corps include: Dr. Donald McCarthy, Minneapolis, general service; and Dr. A. M. Snell of Rochester, special service. * * *

Construction has been started on a new medical center in Saint Paul to be erected at a cost of between $40,000 and $50,000. Located at East Seventh Street and Mounds Park Boulevard, the center is being built for Dr. E. C. Emerson and associates. There will be quarters for ten doctors and a dentist.

* * *

It may not be generally known that material for preparing addresses to the laity on medical subjects, is available to members of the profession at the Bureau of Health Education of the American Medical Association. Material in the form of clippings is loaned to those so requesting for ten-day periods, at no cost except return postage.

* * *

Guest faculty members for the course in obstetrics at the University of Minnesota Center for Continuation Study, April 3 to 5, included: Dr. James E. Fitzgerald, assistant professor of obstetrics at the Northwestern University Medical School; and Dr. Buford G. Hamilton, assistant professor of obstetrics and gynecology at Kansas University, Kansas City, Missouri.

* * *

Dr. William A. Owens has become associated with Dr. L. R. Lima in Montevideo. A graduate of the University of Minnesota Medical School, Dr. Owens interned at the Kansas City hospital. He was on the staff of the General Santa Fe Hospital at Topeka, Kansas, before going to Montevideo. His wife is the former Hildegarde Lima.

* * *

Dr. Philip S. Hench and Mrs. Hench of Rochester left last month for the South. Dr. Hench is spending a week in Havana where he is continuing his investigation on the history of the conquest of yellow fever. On his return he will conduct a clinic on "Gout" at the American College of Physicians in Boston, and will participate in a symposium on "Chronic Arthritis." * * *

Dr. William A. O'Brien, director of postgraduate medical education at the University of Minnesota Medical School, was in Rockford, Illinois, March 25 to speak at Rockford College and before the Rockford Women's Club.

On March 26, Dr. O'Brien participated in the vocational conference at Carleton College in Northfield. He talked on "Opportunities in Medicine."

* * *

Dr. James S. McCartney, Jr., associate professor of pathology at the University of Minnesota Medical School, presented several papers at a postgraduate course in Winnipeg, March 6 and 7. The course was sponsored by the University of Manitoba Medical School and the Winnipeg Medical Society.

On February 11, Dr. McCartney addressed a meeting of the Cerro Gordo Medical Society in Mason City, Iowa. * * *

Dr. Owen H. Wangensteen of Minneapolis, head of the surgery department at the University of Minnesota Medical School, delivered three lectures at the University of Oregon Medical School in Portland, February 13-15. His subjects were: "Studies on the Etiology of Appendicitis," "Practical Aspects of the Therapeutic Problem in Bowel Obstruction" and "The Ulcer Problem Viewed from the Standpoint of Etiology and Therapy." * * *

Speakers at the first annual meeting of the Central Surgical Association held at the University of Michigan Medical School in Ann Arbor, February 28 and March 1, included Dr. J. Grafton Love of Rochester whose subject was "Glossopharyngeal Neuralgia: Diagnosis and Surgical Treatment." Drs. J. M. Waugh and H. B. Macey, also of Rochester, presented papers, entitled "Carcinoid Treatment of the Cecum" and "Surgical Treatment of Axillary Hidrosadenitis Suppurative."

* * *

The serum laboratory in the department of pediatrics at the University of Minnesota has been enlarged, in order to accommodate a new machine which has been developed for desiccating human plasma, making serum available for use as a blood substitute in the treatment of shock and hypoproteinemia. It is possible that the laboratory may be designated by the United States Surgeon General as one of several centers to furnish such plasma serum in war.

* * *

Dr. Karl Wilhelm Stenstrom, professor of biophysics, University of Minnesota Hospitals, spoke to members of the Women's Field Army for the Control of Cancer, March 12, following a conducted tour of the radiation department of the Cancer Institute, of which he is a director. The tour and talk were followed by a dinner at the Center for Continuation Study, at which reports on the recent regional conference in Rochester were presented. In the evening, members attended the meeting of the American College of Surgeons in Northrop Auditorium, at which Dr. George T. Pack of New York City discussed "Cancer is Curable."

* * *

Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota, was in Washington, D. C., April 1, to participate in a conference concerned with deferring medical students from military service. He is a member of the Sub-Committee on Medical Education of the Committee on Health and Medicine, National Council on Defense, which met with officers from the selec-

tive service headquarters. The meeting was a continuation of a conference held in March, which Dr. Diehl also attended.

* * *

The John Scott Medal, given by the city of Philadelphia for outstanding achievement in medical science, has been awarded to Dr. Owen H. Wangensteen, head of the department of surgery at the University of Minnesota.

The award, which also includes a cash gift for $1,000, was made for Dr. Wangensteen's development of a suction syphonage treatment of acute intestinal obstruction. For this work, he also was awarded the Samuel Gross medal by the Philadelphia Academy of Surgery in 1934 when the treatment was still experimental.

* * *

Dr. W. A. Fansler of Minneapolis will be among the guest speakers at the annual meeting of the North Dakota State Medical Association in May in Grand Forks. He will speak May 20 on "Diagnosis and Treatment of Carcinoma of the Bowel." The next day he will lead a round-table luncheon discussion on "Office Treatment of Anorectal Diseases."

Dr. Henry E. Michelson of Minneapolis will also participate in the program. He will talk on diseases of the skin, and will also lead a round-table discussion.

* * *

Dr. Willis H. Thompson of Tennessee has returned to Minneapolis to take over the practice of Dr. Chester A. Stewart who has accepted a position as head of the department of pediatrics at Louisiana State University in New Orleans, Louisiana. Dr. Stewart, who has been clinical professor of pediatrics at the University of Minnesota and director of the University's out-patient department in pediatrics, will leave this summer for New Orleans.

Dr. Thompson, who taught in the University of Minnesota pediatrics department ten years, has for the past two years conducted in forty-five Tennessee cities a postgraduate course in pediatrics, sponsored by the Tennessee State Medical Association.

* * *

Dr. A. V. Stoesser, associate professor of pediatrics at the University of Minnesota Medical School, and Miss Gertrude Carlsrud, nursing instructor in premature infant care, Minnesota State Department of Health, were among the speakers at the Conference of State Directors and Maternal and Child Health Service in Washington D. C., March 24, 25, and 26. Dr. Stoesser's subject was "How to Set Up a State Program for Reducing Infant Mortality." His work at the Minneapolis General Hospital is being used as a foundation for state programs.

Representing the Minnesota State Department of Health at the conference were Dr. Viktor O. Wilson, director of the Division of Child Hygiene, and Dr. E. C. Hartley, consultant.

* * *

With Dr. J. J. Westra's moving from Owatonna to Muncie, Indiana, several changes in location have been made by physicians in southeastern Minnesota.

Dr. S. D. Whetstone of Winona has gone to Owatonna to take over the practice of Dr. Westra, and Dr. W. M. Meyer, Rollingstone, has taken over Dr. Whetstone's practice in Winona. Dr. Meyer for the present will maintain evening office hours in Rollingstone where he has been located since August. He has moved his family to Winona.

Dr. Whetstone, who has been practicing in Winona for three and a half years, moved his family to Owatonna the latter part of February.

* * *

Medical reserve officers, who had been ordered to active duty and whose orders have been revoked, include:

Dr. Arthur F. Dworak, captain, Saint Paul, who had been ordered to Fort Bliss, Texas.

Dr. David Albert Burlingame, first lieutenant, Minneapolis, who had been ordered to William Beaumont General Hospital, El Paso, Texas.

Dr. Henry B. Grimes, major, Madelia, who had been ordered to Fort Ord, Presidio of Monterey, California.

Dr. Abraham B. Rosenfield, captain, Hibbing, who had been ordered to Army and Navy General Hospital, Hot Springs, Arkansas.

Dr. Joseph Herman Sagi, first lieutenant, Minneapolis, who had been ordered to Fort Lewis, Washington.

Dr. Raymond Paul Hawkinson, captain, Robbinsdale, who had been ordered to Fort Des Moines, Iowa.

* * *

That the average ability of students admitted to the University of Minnesota Medical School seems to be definitely increasing, was reported by Dr. Harold S. Diehl, dean of medical sciences, in his report to the President of the University for the period 1938-40.

Although several hundred applications for admission to the Medical School are received each year, facilities necessitate the limitation of students accepted to about one hundred. Applicants who are native residents of Minnesota are given preference, with second preference given to applicants from north central states which have no medical schools of their own. Applicants from other sections of the country are accepted only if there are special reasons for so doing, the most common reason being that they are outstanding students and sons and daughters of alumni of the University of Minnesota.

Under new requirements, which became effective in the fall of 1939, requirements for admission include a minimum of three years of college work and courses in physical chemistry, psychology, genetics and eugenics, in addition to the science work previously required.

* * *

Participating in the scientific programs at the fifth annual meeting of the New Orleans Graduate Medical Assembly in New Orleans, March 3-6, were several Minnesota men.

Dr. Paul A. O'Leary of Rochester presented a paper on "The Eczemas," "The Newer Methods of Treatment of Syphilis" and "Nonspecific Therapy of Cutaneous Disease."

Dr. Leo G. Rigler, professor of radiology at the University of Minnesota Medical School, presented two papers, one entitled "Benign and Malignant Tumors of the Stomach," and the other, "Roentgenological Findings in Acute Abdominal Conditions." He also participated in a symposium on hyperthyroids.

Dr. John R. Paine, assistant professor in surgery at the University of Minnesota, also took part in the program, speaking in place of Dr. Owen H. Wangensteen, head of the surgery department, who could not attend. Dr. Paine presented papers on the following subjects: "Postoperative Strictures of the Common Duct," "Diagnosis of Acute Abdominal Disorders," and "Oxygen Poisoning." He also presented the latter paper before students of Tulane University Medical School. "Intestinal Obstructions" was the title of his talk given at a joint meeting with the Orleans Parish Medical Society, March 7.

* * *

Physicians who will deliver lectures this spring in the Minnesota State Medical Association College Lecture Course are: Dr. F. J. Hirschboeck, Duluth, "On Choosing a Doctor," State Teachers College at Moorhead, April 16; Dr. R. M. Burns, Saint Paul, "What Every Student Should Know About First-Aid," State Teachers College at Bemidji, April 18; Dr. J. R. Meade, Saint Paul, "Eating Wisely and Well," State Teachers College at Bemidji, May 23.

Lectures have already been delivered at St. Scholastica, Duluth; Hamline University; State Teachers College at Winona; Concordia College at Moorhead; State Teachers College at St. Cloud; College of St. Teresa at Winona; St. Mary's College at Winona; Carleton College at Northfield; Luther Theological Seminary at Saint Paul; Gustavus Adolphus at St. Peter; Augsburg College at Minneapolis; State Teachers College at Moorhead; and College of St. Benedict at St. Joseph.

Physicians who lectured were: Drs. D. W. Wheeler of Duluth, A. C. Hilding of Duluth, Harold N. Wright of the University of Minnesota Medical School, E. L. Tuohy of Duluth; F. L. Bryant of Minneapolis; W. A. O'Brien of the University of Minnesota Medical School, J. S. Lundy of Rochester, L. R. Boies of Minneapolis, A. V. Stoesser of the University of Minnesota Medical School, J. R. Meade of Saint Paul, M. J. Nydahl of Saint Paul, and A. E. Hansen of the University of Minnesota Medical School.

W. J. Tomsicek of Saint Paul, professor of Chemistry at St. Thomas' College, also took part in the lecture series, giving several talks on "Quacks and Cure-Alls."

* * *

The following medical reserve corps officers were recently ordered to extended active duty by the Commanding General, Seventh Corps Area.

Dr. David William Quick, Jr., first lieutenant, Bayport, to Fort Leonard Wood, Missouri.

Dr. Maurice W. Quigley, lieutenant colonel, Minneapolis, to Camp Joseph T. Robinson, Arkansas.

Dr. Carl Gerald Caspers, first lieutenant, Minneapolis.

Dr. Andrew W. Shea, first lieutenant, Minneapolis, to Scott Field, Illinois.

Dr. Louis Alfred Benesh, first lieutenant, Minneapolis, to Fort Francis E. Warren, Wyoming.

Dr. Harold G. Benjamin, first lieutenant, Minneapolis, to Fort Knox, Kentucky.

Dr. Bernard Alton Flesche, first lieutenant, Lake City, to William Beaumont General Hospital, El Paso, Texas.

Dr. Harold Herman Joffe, first lieutenant, Duluth, to Fort Riley, Kansas.

Dr. Hyman Katzovitz, first lieutenant, St. Paul, to Fort Francis E. Warren, Wyoming.

Dr. Richard Sidney King, first lieutenant, Cass Lake, to Fort Francis E. Warren, Wyoming.

Dr. Carleton Walter Leverenz, first lieutenant, St. Paul, Fort Warren.

Dr. Russell C. Lindgren, first lieutenant, Minneapolis, Army and Navy General Hospital, Hot Springs, Arkansas.

Dr. James Joseph Morrow, major, Austin, to Fort Leavenworth, Kansas.

Dr. Hanns Carl Schwyzer, first lieutenant, St. Paul, Fort Leonard Wood, Missouri.

* * *

In Memoriam

William M. Chowning

Dr. William M. Chowning, Minneapolis, died February 8, 1941, at the Veteran's Hospital, Minneapolis.

Born in Millerburgh, Illinois, in 1873, Dr. Chowning was graduated from Knox College, Galesburg, Illinois, and received his B.A. degree from Johns Hopkins University. In 1901 he graduated from the medical school of the University of Minnesota and taught bacteriology and pathology there. He investigated a spotted fever epidemic in the Bitter Root Valley of Montana in 1907.

Dr. Chowning had been a member of the surgical staff of the General Hospital, Minneapolis. He was a major in the World War and organized a war emergency hospital and dispensary for government employes in the District of Columbia. Later he was made chief of the surgical service and commanding officer of base hospital No. 119 and in October, 1918, he was stationed at Savigny, France.

Dr. Chowning was a member of Alpha Kappa Kappa medical fraternity, was a mason and had been a member of the Hennepin County Medical Society until 1923.

Dr. Chowning is survived by his widow and two sons, and two daughters by a former marriage.

Joseph A. Roy

Dr. J. A. Roy of Red Lake Falls died suddenly while making a professional call, January 30, 1941. He was a member of the Red River Valley Medical Society. His death, which came while he was caring for the sick of his community, bespeaks his faithfulness to their trust in him.

Dr. Roy was born at St. Anaclet, Quebec, Canada, December 10, 1888. His preliminary education was obtained at the Seminary of Rimouski, Quebec. He later attended the College of Medicine at the University of Montreal, from which school he graduated with his

doctor's degree in 1913. He started the practice of medicine at Pelee Island on Lake Erie, leaving there to go to Saint Paul, Minnesota, in 1916. After passing the Minnesota State medical examinations, he opened an office in Kensington, Minnesota, where he practiced until 1919, when he moved to Argyle. He continued there until, in 1922, he decided Red Lake Falls would be his final location. This decision was a happy one, both for himself and his community.

Dr. Roy not only believed in serving his community well from the medical standpoint, but also believed that a doctor should take active interest in the civic and fraternal affairs as well. To render practical value to that statement, he was elected mayor of Red Lake Falls in 1931, and served in that capacity until his death terminated his tenure of office. He was active politically also on a national scale and in 1928 was elected Red Lake County Democratic committeeman, and as such attended the inauguration of President Roosevelt in 1933. His activities extended to fraternal matters also, and his leadership in all matters he entered into was finally rewarded by being elected to the office of State Vice-Chief Ranger of the Catholic Order of Foresters in 1930.

Dr. Roy therefore typified the American general practitioner. He was faithful to his trust in matters medical, but felt it also his duty to cultivate his talents in matters civic and fraternal. His loss will be keenly felt by his numerous medical friends and by his community.

Charles Andrew Erdmann

The passing on February 19, 1941, of Dr. Charles A. Erdmann, formerly of the Department of Anatomy at the University Medical School, saddened the several thousands of graduates who had studied anatomy under him.

Dr. Erdmann was born August 3, 1866, at Milwaukee, Wisconsin, the son of Andrew and Elizabeth Fuch Erdmann. He graduated from the University of Wisconsin in 1887 and obtained his M.D. at the University of Minnesota in 1893. For three years as an undergraduate he served as a student assistant in anatomy. Immediately upon graduating he became affiliated with the Department of Anatomy as Demonstrator until 1894. He was Demonstrator in Anatomy and Assistant in Medicine from 1894 until 1898, Assistant Professor of Anatomy in 1898 and 1899, and full professor in 1899. In 1913 he received the title of Associate Professor of Applied Anatomy, which he held until he retired in June, 1936, at the age of seventy. Upon retirement Dr. Erdmann had been active in teaching anatomy at the Medical School for forty-three years, a unique record for a member of the medical school faculty.

Dr. Erdmann was a member of Acacia and of the Nu Sigma Nu medical fraternity. He was also a member of the Hennepin County Medical Society, becoming an affiliate member in 1926. He was elected to honorary membership January 1, 1929.

He was interested and active in Masonic work, having been a member of the University No. 316 A. F. and A. M. Scottish Rite and a life member of the Zuhrah Temple. He was elected an honorary thirty-third degree Mason in 1911.

Surviving Dr. Erdmann are his wife, Caroline, a daughter, Elizabeth, two sons, Robert of Minneapolis and Charles Edgar of Denver, Colorado, and one grandson.

Dr. Erdmann made teaching his life work and loved it. This was evident to the many students who studied under him, with considerable pleasure and interest, a subject ordinarily considered heavy and dull. He was intensely interested in each individual student and was pleased and proud of every success and honor each may have attained and he won the affection of his many students.

The following poem by Louis Burton Woodward was particularly loved by Dr. Erdmann and a copy of the poem was kept on his desk:

Because I would be young in soul and mind
Though years must pass and age my life constrain,
And I have found no way to lag behind
The fleeting years save by the magic chain
That binds me, youthful, to the youth I love,
I teach.

Because I would be wise, and wisdom find
From millions gone before whose torch I pass,
Still burning bright to light the paths that wind
So steep and rugged, for each lad and lass
Slow climbing to the unrevealed above,
I teach.

Because in passing on the living flame,
That ever brighter burns the ages through,
I have done service that is worth the name
Can I but say "The flame of knowledge grew
A little brighter in the hands I taught,"
I teach.

Because I know that when life's end I reach
And thence pass through the gates so wide and deep
To what I do not know, save what men TEACH
That the remembrance of me men will keep
Is what I've done; and what I have is naught,
I teach.

(Louis Burton Woodward.)

ORIGIN OF GREAT CLINICIANS

There is no better student than the son of a medical father if the boy's heart is in the work, but none is worse than he who, not caring for, or even disliking, the practice of medicine, is urged on by a medical parent to qualify in order to take his place. Better even than the student who, having family traditions, takes to medicine almost by instinct is the boy who, lacking any such associations, determines, whilst still a child, that he will be a doctor. For, in this last case, he may have more than an ideal to study and to advance the science of medicine—he may have a real call to heal the sick and alleviate human suffering. It is from this class that the truly great clinician is derived. Often these students are what might be termed freaks in their families. They appear in every social stratum, and their early decision to become doctors seems often to be unrelated to any outside circumstances. F. Wood Jones, in *Doctors in Shirt Sleeves,* edited by Sir Henry Bashford, London, Kegan Paul, Trench, Trubner & Co., Ltd., 1939.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR APRIL

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Professor of Preventive Medicine and Public Health, Medical School, University of Minnesota.

April 5—Cancer in Women
April 12—Radium and X-ray
April 19—When Cancer Begins
April 26—Tumors of the Mouth

STATE MEETING

More than 3,000 physicians from the northwest states are expected to attend the eighty-eighth annual meeting of the Minnesota State Medical Association to be held May 26, 27 and 28, at the Saint Paul Auditorium.

Preliminary arrangements for this event call for an unusually timely program, an extensive scientific exhibit and attractive social events.

Railroad surgeons of the Great Northern and Northern Pacific Railways will join with the Medical Association for this meeting, the Great Northern Railway Surgeons' Association holding its own regular annual meeting concurrently and all uniting on Tuesday, May 27, for an entire day's program on the subject, "Surgery of Trauma."

Four distinguished out-of-state speakers will speak at this session, including Drs. Thomas M. Joyce of Portland, Clinical Professor of Surgery at the Oregon State University Medical School; Sumner Koch of Chicago, Associate Professor of Surgery at the Northwestern School of Medicine; H. H. Kessler, of Newark, New Jersey, and Leroy Sante of St. Louis, Professor of Radiology at the St. Louis University School of Medicine. Dr. Joyce and Dr. Koch are appearing on the program under the auspices of the Great Northern and the Northern Pacific surgeons, respectively. Dr. Sante will give the annual Russell D. Carman Memorial Lectureship under auspices of the Minnesota Radiological Society as part of this program.

Among other well-known guests are Dr. Edward D. Churchill, John Homan Professor of Surgery at Harvard Medical School; Col. G. C. Dunham, Executive Secretary of the Medical Committee of the National Defense Council, and Mr. C. M. Utley, national president of the Foreign Policy Association. Mr. Utley will speak at the Minnesota Alumni dinner, Monday night, May 26, and Col. Dunham will be principal speaker at the annual banquet on Tuesday.

The golf tournament is scheduled for Sunday, May 25, at the White Bear Yacht Club and on Monday night, following last year's successful precedent, there will be an Open House for all who register and their guests in the Auditorium arena. Exhibits will be open for inspection and for entertainment. There will be a Gay Nineties show and refreshments.

Tuesday and Wednesday noons will be devoted to round-table discussion luncheons, ten on each day, with other reunions and luncheon meetings on Monday.

The meeting will close on Wednesday afternoon, May 28, with a general military session at which physical findings among selectees, the nutrition problem in defense and the part played by physicians in defense and in the fighting forces will be discussed. Col. Dunham is scheduled to address this meeting, together with other medical defense authorities.

AMERICAN ASSOCIATION OF OBSTETRICIANS, GYNECOLOGISTS AND ABDOMINAL SURGEONS

The American Association of Obstetricians, Gynecologists and Abdominal Surgeons offers again an award known as "The Foundation Prize" consisting of $150.00 to the successful contestant who shall submit the best thesis as judged by the Committee on Award. The competition is open to interns, residents or graduate students in obstetrics, gynecology or abdominal surgery, and to practicing physicians. Manuscripts must be submitted before June 1, 1941.

Further information may be obtained from Jasper R. Bloss, M.D., 418 Eleventh Street, Huntington, West Virginia.

AMERICAN COLLEGE OF SURGEONS

Sectional Meeting

The sectional meeting of the American College of Surgeons held in Minneapolis on March 10, 11 and 12, 1941, did not receive the attention which it deserved from surgeons in this state and the adjoining states because of the inclement weather.

The local committees organized wet and dry clinics for general surgery and the surgical specialties which were as elaborate and numerous as those at the Clinical Congress of the American College of Surgeons. Subjects under discussion included fractures, cancer and hospital administration. The hospital conference held many sessions, some of them beginning as early as 7:45 in the morning. Every phase of hospital management was discussed.

The panel discussions were well organized and well attended, the leaders being men and women prominent in the surgical profession. The same can be said for the scientific exhibits. The American College of Surgeons is interested in the work of the young surgeon, and at the University of Minnesota Hospitals the younger men were encouraged to present research problems of general interest.

Although many wet clinics were held in the various hospitals of Minneapolis, the dry clinics seemed to attract the larger number of surgeons and seemed to be a more effective teaching medium than operative clinics. It was suggested that at future meetings the

rooms located in the headquarters hotel used by the College for panel discussions might also be utilized in the morning hours by the various hospital staffs for dry clinics to obviate transportation of the surgeons to the various private hospitals about the city. If this plan is put into effect, the cancer and fracture clinics could be held in two of the large public hospitals.

The committees on arrangements headed by Dr. W. A. Hanson with the assistance of the Hennepin County Medical Society deserves great praise for the excellent arrangements and the instructive clinics and panel discussions.

A Chapter of the American College of Surgeons was organized during this sectional meeting. It is hoped that members of the College in the Twin Cities who practice the various specialties may become better acquainted since at the present time these various surgical specialties have individual meetings. Dr. F. A. Olson of Minneapolis was elected Chairman of this new chapter.

Gilbert J. Thomas, M.D.
Member, Board of Regents
American College of Surgeons

ELIAS POTTER LYON MEMORIAL LECTURES

The second annual Elias Potter Lyon Memorial Lectures in the Physiological Sciences will be delivered at the University of Minnesota Medical School, May 1 and 2, at 8 p. m. by Professor Ernst Gellhorn of the Departments of Physiology and Psychiatry of the College of Medicine of the University of Illinois. The lectures will be given in the Medical Sciences Amphitheater.

Professor Gellhorn's lecture subjects will be: "The Neurophysiological Basis of Some General Adjustment Reactions," and "Investigations on the Central Excitation of the Autonomic Nervous System and Their Significance for the Problem of Schizophrenia."

WILLIAM ROOT LECTURE

Dr. Arno B. Luckhardt of the department of physiology at the University of Chicago, will deliver the William Root Lecture, sponsored annually by the Alpha Omega Alpha medical fraternity, in the University of Minnesota Medical Amphitheater, Tuesday, April 29, at 8:15 p. m.

The subject of his lecture will be "Dr. William Beaumont and the Medical Epoch of the Northwest Territory."

ENDOCRINOLOGISTS FORM SOCIETY

Dr. Leo T. Samuels, assistant professor of physiological chemistry at the University of Minnesota Medical School, has been named chairman of the newly organized society of endocrinologists. Meeting at the Coffman Memorial Union, March 12, members of the society heard Dr. Edwin C. Hamblen, associate professor of obstetrics and gynecology at Duke University School of Medicine.

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL LECTURE

Dr. Lucien Brouha, physiologist on the Grant Foundation at Harvard University and professor of human biology at the University of Lieges, Belgium, will lecture at the University of Minnesota Medical School, April 22. He will give an illustrated lecture on the functions of the autonomic nervous system.

COURSE IN SURGICAL PATHOLOGY

The Pathology Department at the University Medical School will give a summer short course in surgical pathology from June 16 to July 25. The course will be similar to that given last year, except that it will occupy twenty instead of fifteen hours each week. In addition to the regular course those enrolled will attend a tumor clinic each week and an x-ray demonstration of bone tumors.

The course is open to members of the profession. Those interested may communicate with Dr. J. S. McCartney, Department of Pathology, University Medical School, Minneapolis.

BLUE EARTH COUNTY MEDICAL SOCIETY

Fifty years as a family doctor were reviewed by Dr. J. A. Hielscher of Mankato at the February meeting of the Blue Earth County Medical Society.

A member of the first class graduated from the University of Minnesota Medical School in 1891, Dr. Hielscher will complete a half century of practice in Mankato in June.

In his talk, Dr. Hielscher recalled the diphtheria epidemic of the '90's; how he went to Chicago in 1896 to see an appendectomy performed after reading about it for the first time; how when he first started practicing, he harnessed the team to his buggy, heated bricks for his feet and wrapped up in buffalo robes before starting out on a winter call.

The passing of the "good" old days brought from Dr. Hielscher regret for only one phase. "The old family physician is disappearing—and I think it is too bad."

MINNEAPOLIS ACADEMY OF MEDICINE

At the meeting of the Minneapolis Academy of Medicine (formerly the Minneapolis Clinical Club), March 13, at the Minneapolis Club, Dr. Edwin C. Hamblen, associate professor of obstetrics and gynecology at Duke University School of Medicine and chief of the endocrine division of Duke Hospital, Durham, North Carolina, addressed the members on "The Sterol Family."

THE MISSISSIPPI VALLEY MEDICAL SOCIETY

The Mississippi Valley Medical Society offers annually a cash prize of $100.00, a gold medal and a certificate of award for the best essay on any subject of general medical interest (including medical

economics) and practical value to the general practitioner of medicine. Contestants must be members of the American Medical Association who are residents of the United States. The winner will be invited to present his contribution at the next annual meeting of the Mississippi Valley Medical Society at Cedar Rapids, Iowa, October 1-3, 1941. Further details may be obtained from Dr. Harold Swanberg, secretary, 209 W.C. U. Building, Quincy, Illinois.

MINNESOTA PATHOLOGICAL SOCIETY

The program for the meeting of the Minnesota Pathological Society, April 22, follows:

"Pathologic Physiology of the Kidney"—Dr. E. T. Bell

"Vitamin B_1 Deficiency from Fish Diets"—Drs. R. G. Green and C. A. Evans.

SCOTT-CARVER MEDICAL SOCIETY

The Scott-Carver Medical Society met at the Mudbaden Sanatorium in Shakopee, March 11. Dr. Frederick Schaaf of Minneapolis spoke on "Avitaminosis."

WASHINGTON COUNTY SOCIETY

The Washington County Medical Society held its regular monthly meeting at Stillwater, March 11. Dr. Charles E. Rea of Saint Paul addressed the members on the subject of "Cryptorchidism." Dr. B. J. Lannin of Minneapolis, a Fellow in Surgery at the University of Minnesota Medical School, was a visitor.

WINONA AND WABASHA COUNTY SOCIETIES

The tenth annual joint meeting of the Winona and Wabasha County Medical Societies was held at Buena Vista Sanatorium in Wabasha, March 3.

Thirty-one were served at the dinner. The program was arranged by Dr. R. R. Hendrickson, superintendent of the Sanatorium. Dr. H. W. Satterlee of Lewiston, president of the Winona County Medical Society, presided. The addresses were:

An outline of the setup and work done by the medical department of the State Division of Social Welfare. H. E. Hilleboe, M.D., Medical Director.

"Treatment of Some Common Dermatoses"—Dr. F. W. Lynch, M.D., Saint Paul.

"Physical Examinations under the Selective Service Act"—Lt. Col. Hullsick, State Medical Director.

A talk on present trends in medicine and plans of the State Medical Association.—B. J. Branton, M.D., President.

WOMAN'S AUXILIARY

Mrs. M. A. Nicholson, Duluth, Minnesota, *President*
Mrs. E. V. Goltz, 2259 Summit Avenue, Saint Paul, *Publicity Chairman*

Only a few more weeks and the members of the Woman's Auxiliary of the American Medical Association will be arriving in Cleveland for their annual convention, June 2-6. Have you made your reservation? If not, send your request *at once* to Dr. Edward F. Kieger, Chairman of Committee on Hotels and Housing, 1604 Terminal Tower Building, Cleveland.

* * *

Mower County Auxiliary held a meeting February 24 at the home of Mrs. F. W. Molgren, in Austin. The regular business meeting was followed by a luncheon and bridge.

* * *

The home of Mrs. O. V. Johnson, Fergus Falls, was the meeting place for members of the *Park Region Auxiliary* recently. The doctors and their wives enjoyed dinner together and after the dinner the Auxiliary members held their business meeting and social hour. Mrs. Norman Baker of Fergus Falls has been selected State Health and Summer Round-Up chairman for the National P.T.A.

* * *

Dr. and Mrs. J. B. Vail and son have left for San Diego, California, where Dr. Vail will be in the Army service. Mrs. Vail is a member of the Park Region Auxiliary and shared honors with Dr. Vail recently at a farewell party which was given by Dr. and Mrs. E. C. Perreten.

* * *

Wabasha County Auxiliary recently elected Mrs. Earle Ellis of Elgin, president. The meeting was held at the home of Mrs. B. J. Bouquet. Mrs. D. G. Mahle of Plainview is the retiring president. Mrs. B. J. Bouquet was elected vice president for another year and Mrs. L. F. Race of Plainview was elected secretary-treasurer to succeed Mrs. M. F. Campion of Lake City. The Auxiliary recently awarded a one dollar prize to Florence Walch of Plainview for her essay on "Tuberculosis," which was judged the best of 160 essays submitted by the five Wabasha County schools.

* * *

The Merchants Hotel at Morris was the scene of the regular meeting of the *West Central Auxiliary,* March 6. After the dinner meeting with the doctors the Auxiliary members met at the home of Mrs. F. W. Behmuler, where Mrs. M. A. Nicholson, state president, was the guest of honor.

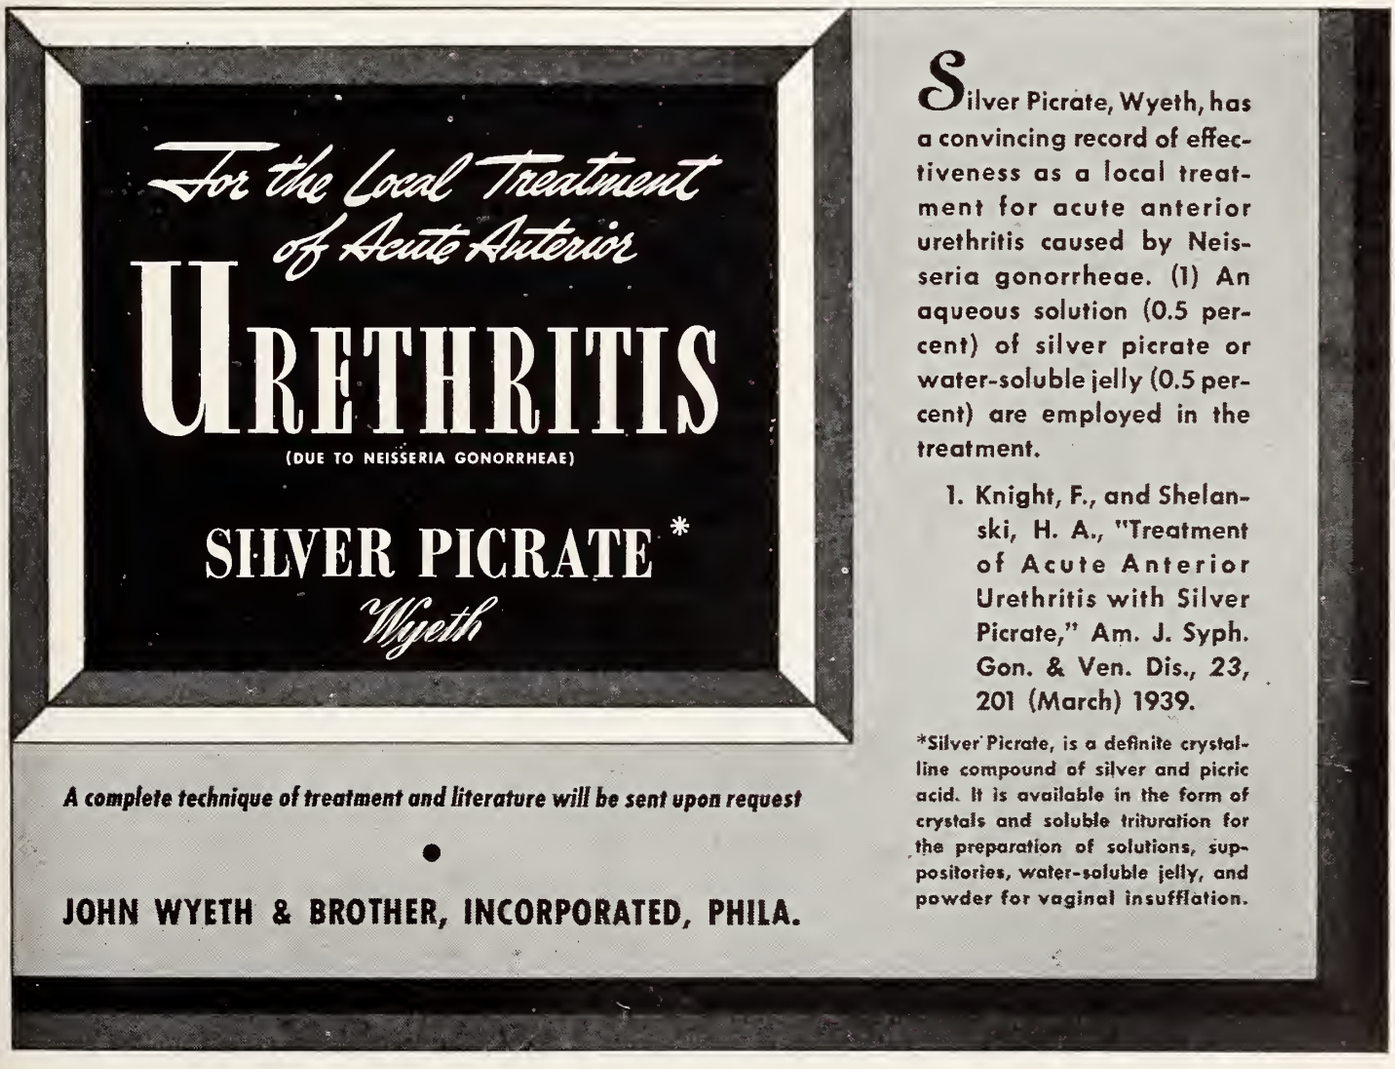
An astonishingly large percentage of intelligent people conceive of available knowledge as comprising nearly all that may be known. It has required the shock of many recent discoveries in physics, chemistry, astronomy and biology to make clear the fact that our acquaintance with much that is nearest to us is still distinctly inadequate.—John C. Merriam in *Think.*

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

IT IS YOUR LIFE. Keep Healthy, Stay Young. Live Long. Max M. Rosenberg, M.D., Member American Medical Association and New York County Medical Society. Formerly in charge of Clinical Laboratory O.P.D. Beth Israel Hospital, Clinical Assistant Internal Medicine, Beth Israel Hospital, Clinical Assistant in Pediatrics, Gouverneur Hospital. 450 pp. Illus. Price $2.50. New York: The Scholastic Book Press, 1940.

This, enthusiastically proclaims the jacket, differs from the numerous "health and medical advice books" which undertake to teach the reader to diagnose and treat every imaginable disease under the sun, from apoplexy to pinworms. To be really comprehensive it might have made the range to include everything from the Egyptian AAA disease to the Hebrew zaarath, but let that pass; we are not pedantic.



The book contains a lot of fairly good advice on personal hygiene, diet and the cultivation of correct mental attitudes. On the other hand, in his evident desire to reform the race the author goes far afield when he undertakes to impress the baleful effect of various drugs. His attack on the demon rum carries us back to the days of the hobnail liver pictures in the school books. We are not aware of any experienced pathologists who would agree with the author's statement that "autopsies on thousands of cases all over the world have shown that in habitual drinkers all the organs of the body without exception undergo degeneration" followed by the gruesome details.

The author denounces the use of sulfanilamide in a way that would make a patient distrust or discharge a physician who prescribed it and in one place actually advise the reader not to let his doctor give him a certain drug. On the whole, however, he is loyal to his own profession and emphasizes the value of the advice of a competent physician; the latter will have an easier time with his patient if he does not have to argue against some of the pontifical statements in the book.

GILBERT COTTAM.

ILLUSTRATIVE ELECTROCARIOGRAPHY. Julius Burstein, A.B., M.D., Associate Electrocardiographer and Chief of the Cardiac Clinic, Morrisania City Hospital, New York. Originally written by the late Joseph H. Bainton, A.B., M.D., and Julius Burstein, A.B., M.D. Second edition. 292 pages. 106 plates. Price, $4.50. New York, London: D. Appleton-Century Company, Incorporated, 1940.

Beautifully, clearly, concisely, illustratively written. Simple descriptive style, easily understandable; grada-

tion from the simplest of fundamentals through the latest and completest survey of the entire field of electrocardiography.

The new fields of coronary occlusion; precordial (chest) leads; verbatim report on the "Standardization of Precordial Leads" from the American Heart Association and its supplementary report on "Multiple Precordial Leads" are exhaustively and understandably presented. The serial presentations are illuminating and instructive.

The reviewer hopes for a more extensive treatise of electrocardiography in childhood, rheumatic heart disease progress, congenitally defective heart and the miscellaneous group. The third edition will be welcomed, with a shorter publication interval.

LILLIAN L. NYE, M.D.

SYMPOSIUM ON THE SYNAPSE. Herbert S. Gasser, Joseph Erlanger, Detlev W. Bronk, Rafael Lorente de Nó and Alexander Forbes. 113 pages, Illustrated with 25 diagrams and graphs. Springfield, Illinois, and Baltimore, Maryland: Charles C. Thomas, 1939.

The material contained in this booklet formed the subject matter of a symposium on the mechanism of synaptic transmission held in Toronto on April 29, 1939, under the auspices of the American Physiological Society at its annual meeting. Originally published in the *Journal of Neurophysiology* (2:361-472, 1939), it is now reproduced in this form for permanent use, with considerable revision and extension of the papers of Bronk and Lorente de Nó. The voluminous references are properly arranged in alphabetic order and there is an adequate index. It is "Dedicated with respect and affection to Charles Scott Sherrington, O.M., who introduced the concept of The Synapse, as well as the word itself, into the literature of neurophysiology."

The symposium was made up of the following components:

H. S. Gasser, who is Director of the Rockefeller Institute for Medical Research in New York City and acted as chairman of the symposium, contributed the article on axons as examples of nervous tissue, with prominent mention of the recent work of Eccles and Pritchard on the action potential of motorneurones, published in the *Journal of Physiology* (89:43-45, 1937).

Joseph Erlanger, Professor of Physiology in Washington University, Saint Louis, discussed the initiation of impluses in axons and hoped that the evidence he presented would indicate that an electrical mechanism could account for synaptic transmission whatever else might be involved.

Detlev W. Bronk, Director of the Eldridge Reeves Johnson Research Foundation and of the Institute of Neurology, University of Pennsylvania, Philadelphia, read the third paper, on synaptic mechanisms is sympathetic ganglia, without "desire to defend either the acetylcholine hypothesis or the theory of excitation by circulating currents from the presynaptic terminations. On the other hand I do not wish to oppose them or to adopt a dualistic hypothesis. If it be necessary to do more at this time than describe the phenomena of transmission and relate them into a consistent scheme, I would argue for a pluralistic theory."

Rafael Lorente de Nó, co-worker of Gasser in the Rockefeller Institute, contributed the fourth article, on transmission of impulses through cranial motor nuclei, much the most comprehensive of the five contributions and occupying more than one-half of the space in the book. He mentioned many experiments which have revealed data that have significant bearing on the problem of synaptic transmission of impulses to motorneurons, which help to state but are insufficient to solve the problem.

Alexander Forbes, Professor of Physiology in Harvard Medical School, summed up and commented on the issues involved. The entire symposium revolved around the controversy between those who advocate the original electrical theory of transmission through synapses and those who believe in the newer idea of chemical stimulation, called elsewhere by Walter B. Cannon the electragonists and the chemagonists.

While highly abstruse it should be interesting to anyone who is familiar with the fundamentals of neurophysiology to follow these trained workers into fastnesses of uncharted terrain. That the solution is not yet in sight by no means detracts from the fascination of listening to the arguments and experimental evidence of the controversialists.

GILBERT COTTAM.

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

PSYCHIATRISTS IN CHARGE
Dr. Hewitt B. Hannah
Dr. Joel C. Hultkrans

BLOOD TESTS TO PROVE NON-PARENTAGE*

REPORT OF SPECIAL COMMITTEE

THE president of this association was prompted to appoint this Committee on "Blood Tests to Prove Non-Parentage" by the report of the Committee on Jurisprudence and Law Reform of the Minnesota State Bar Association at its meeting last July in which it was proposed that a bill be submitted to our legislature, modeled after the Wisconsin law, making blood tests admissible in evidence in matters involving paternity. The Wisconsin statute grants the court the power to direct that the complainant, the child, and defendant submit to blood tests to determine whether or not defendant can be excluded as a possible father of the child, makes the results of the tests admissible in evidence only in cases where definite exclusion is established, imposes the cost of such tests upon the county and provides further that, if one of the parties refuses to submit to a test when ordered, such fact shall be disclosed upon trial unless good cause to the contrary is shown.

In 1900 Dr. Landsteiner, of the Rockfeller Institute of Medical Research, discovered that four different groups of human blood result from the varying occurrence of two agglutinable substances in the red blood cells, which substances were designated *A* and *B*. The four groups are:

1. Group A—persons having only substance *A* in their blood cells (40% of population).
2. Group B—persons having only substance *B* (15% of population).
3. Group AB—those having both substances *A* and *B* (5% of population).
4. Group O—those having neither *A* nor *B* (40% of population).

Dr. Landsteiner at the same time also announced that the blood serum contained two substances, called agglutinins, designated by Greek letters *a* and *b*, meaning anti-*A* and anti-*B*. Group *A* persons have agglutinogens *A* and agglutinins *b*. Group *B* persons have agglutinogens *B* and agglutinins *a*. Agglutinins *a* (found in group *B* persons and meaning anti-*A*) when mixed with the blood of a group *A* person, cause the latter's red blood cells to "bunch," "clump" or agglutinate, but, when mixed with the blood of a group *B* person, cause no unfavorable reaction. Agglutinins *b* (found in group *A* persons and meaning anti-*B*), when mixed with the blood of a group *B* person, cause the latter's red blood cells to "bunch," "clump" or agglutinate but cause no unfavorable reaction when mixed with the blood of a group *A* person.

This discovery was of the greatest importance in blood transfusions. Before that time fatal reactions frequently occurred in blood transfusions. This was puzzling because it was assumed that the blood of individuals of the same species must be identical, but Landsteiner solved this mystery when he discovered the existence of four different human blood groups. These four blood groups are found in individuals of all races. Today, as you know, the blood of willing donors is tested to obtain the proper blood grouping before a transfusion is made. For this discovery, Dr. Landsteiner won the highest recognition of science, in 1930, the Nobel Prize.

His discovery was soon to have a new significance. A preliminary study by Ottenburg and Epstein suggested the heredity nature of these blood groups. Van Dungern and Hirszfeld made the first extensive study in 1910 and in 1925 Bernstein evolved the law now accepted.

*Report to the Minnesota County Attorneys' Association at its annual convention in Duluth, Minnesota, December 27, 1940, made by the Committee appointed by the President of the Association on "Blood Tests to Prove Non-Parentage."

Thus we have the following classification and composition of blood groups:

Groups	Cells (agglutinogens)	Serum (agglutinogens)
O	——	a and b
A	A	b
B	B	a
AB	A and B	——

From this discovery two laws of heredity of blood groups can be stated:

1. The agglutinogens *A* and *B* cannot appear in the blood of a child unless present in the blood of one or both parents. This is known as the law of Van Dungern and Hirszfeld.

2. Individuals of group *AB* cannot have children of group *O* and group *O* individuals cannot have group *AB* children. This is known as the Bernstein law.

A test of 20,000 children has not revealed a single exception to the first law of heredity. The Committee appointed by the American Medical Association, consisting of Dr. Landsteiner of the Rockefeller Institute of Medical Research of New York, whom I have mentioned, Dr. Wiener of New York, one of the best recognized authorities on the subject, and Dr. Hektoen, a Chicago expert, recently recommended to the House of Delegates of the American Medical Association that this law of heredity be accepted without reservations. This report was adopted by that Association.

Under the Bernstein law, 4000 mothers of group *O* with their 5000 children have been tested and not a single child was found to belong to group *AB*, and 600 group *AB* mothers with their 1000 children have been examined and among these there was only one real exception to Bernstein's theory. In this case, the mother belonged to group *AB* and the child to group *O*. The American Medical Association Committee therefore recommended in such cases that it should be stated merely that parentage is extremely unlikely or that parentage is excluded with a high probability, bordering on certainty. Under the language of the Wisconsin law, under such findings, there would not be a definite exclusion and, accordingly, the results of the tests could not be used in evidence and defendant could not have the benefit of them.

More recently in 1928, Dr. Landsteiner, with the aid of Dr. Levine, discovered two new agglutinogens in the red blood cells. These are known as *M* and *N*. They had not been previously observed because normal human or animal sera do not contain agglutinins against *M* and *N* substances. Therefore, it is necessary to inject human blood into animals such as rabbits, or other animals such as cats or goats, in order to obtain sera with agglutinins *M* and *N*. The *M* and *N* factors are entirely independant of *A* and *B* factors. Unlike the *A* and *B* factors it is not necessary to consider them in blood transfusions. The red blood cells of a person may be without either the *A* and *B* substances, but they always have substances *M* or *N* or both. A test of more than 50,000 persons has not disclosed a single exception. In reference to these substances all persons fall into three types. (The use of the word "type" is recommended by the Committee of the American Medical Association to distinguish it from the word "group" as used in reference to substances *A* and *B*). The three types are:

1. Type M—person having only substance *M* in their blood (25% of population).
2. Type N—persons having only substance *N* in their blood (25% of population).
3. Type MN—persons having both *M* and *N* substances in their blood (50% of population).

The *M* and *N* factors are also hereditary and are always inherited. The tests prove two laws of heredity:

1. Agglutinogens *M* and *N* cannot appear in the blood of a child unless present in one or both parents.

2. Type *M* parents cannot have a type *N* child and type *N* parent cannot have type *M* child, regardless of the type of the other parent.

Seven thousand tests revealed no exception to these laws. The American Medical Association Committee, previously referred to, therefore, states in its report that the foregoing laws as to *M* and *N* types can be accepted without qualification.

There are, however, sub-groups of groups *A* and *AB* which are believed to be hereditary but there have been certain exceptions to that theory in a few recent reports. Furthermore the technic in determining sub-groups offer certain dif-

ficulties. The American Medical Association Committee feels, therefore, that the application of sub-groups *A* and *AB* is not well enough established to be used at present as a routine procedure. In other words, the results of the tests in such cases would be regarded as inconclusive and not admissible in evidence.

Carefully prepared tables are available showing the possible groups and types to which the father must belong if the group and type of the mother and the child are known. If the father does not belong to one of these groups or types, then he is definitely excluded as the possible father of such child. For instance, if the child in question has substance *A* in its blood cells and its mother does not have, then its father must have substance *A* in his blood cells. If the test shows that the defendant does not belong to group *A*, he is definitely excluded. If, however, he has substance *A* in his blood cells, the test would say that he could be the father of the child. On the other hand, if the child had substance *B* in its blood cells and the mother did not, then the alleged father must have substance *B* in his blood cells; otherwise he would be definitely excluded. But if the test for *A* and *B* does not exclude the defendant as a possible father, the more difficult test for *M* and *N* must be made. If, for instance, the child has only substance M in its blood cells, it follows that only a person belonging to type *M* can be a possible father. Therefore, if the test shows that the defendant belongs to type *N*, he would be definitely excluded as a possible father. But if neither test excludes the defendant as a possible father, the answer of the test would be that he could be the father of such a child. In other words, the test operates as negative proof—never as affirmative proof. It cannot say to the defendant, "You are the father of this child." It can say to the defendant, in a limited number of cases, "You cannot be the father of this child." Blood tests cannot prove paternity. They can disprove paternity in one out of every three falsely accused persons. The *A* and *B* test can exclude 16 per cent of the falsely accused and the *M* and *N* test about doubles the percentage.

Medical authorities are universally agreed that, within the limits explained, blood tests are absolutely reliable when made by thoroughly qualified experts. The *Journal of American Medical Association* of July 27, 1940, states:

> There would seem to be no justification for further hesitancy on the part of the courts to accept as scientifically sound the results of blood grouping tests to the extent that they disprove the possibility of paternity.

Blood tests in paternity matters have received much consideration in the law reviews and law journals of our country during the past five or six years. Nearly every law journal and law review of the larger universities have had exhaustive articles on the subject. Your committee has read many of them. All uniformly strongly advocate the use of blood tests. We are informed that this is the view of the law reviews and journals throughout the country. In fact most of these reviews are impatient with the delay of the courts in accepting the reliability of blood tests, *Minnesota Law Review* leading the field in this respect (see "Blood Grouping Tests and more 'Cultural Lag'" 22 Minn. Law Rev. 836).

The Oregon Law Review for April, 1938, page 190, states:

> Upon the basis of this unanimous acceptance of the A-B and M-N blood tests by the courts in civil and criminal cases in the new and old worlds, there seems to be no valid objection to the acceptance of this valid scientific fact by the courts of the United States. Blood tests are incontrovertible evidence and absolutely conclusive within their limits.

Strangely enough, though blood groups and types, the laws of their heredity, and their significance, were all discovered in America, Europe was the first to make the earlier and greater use of them in paternity cases. The first case of blood tests in paternity matters in the courts in Europe occurred in 1926. Our first was in 1931 in Pennsylvania. Prior to 1930 when the *M* and *N* factors were first discovered, European courts had already had nearly 7,000 cases of blood tests under the A and B groups. By 1932 Europe started using the *M* and *N* tests discovered only a few years before. Up to April, 1938, Europe had had nearly 9,000 recorded cases, with nearly 900 exclusions. These were principally in Germany (5,430); Sweden (859); Austria (829); Danzig (756) and Denmark (669). Up to the same time the United States had had 213 cases with thirty exclusions. Of these, 181 were in New York state and nineteen in Ohio, with a percentage of exclusion in the United States of 9.8

per cent as compared with 9.7 per cent in Europe. Since 1930 when the *M* and *N* test was discovered there have been 2,095 cases in Europe with 300 exclusions or 14.2 per cent. Tests are quite regularly used in the countries just mentioned. Austrian courts refuse to protect a litigant who refuses to submit to a blood test. France, Italy and Spain, however, make little, if any, use of the blood tests.

In the United States, courts have availed themselves of the blood test much more slowly. The courts in many states as well as our federal courts held they are without authority to order a blood test without a statute specifically authorizing it. Some states, however, notably Ohio and South Dakota, held that the court had inherent power to order such tests. New York lead the way in 1935 by passing a statute providing for blood tests in parentage cases and making the result of such test admissible in evidence, if it definitely established exclusion. In the same year, Wisconsin passed a similar law which is now proposed as a model for Minnesota. It was sponsored by Dr. Levine, one of the discoverers of the *M* and *N* factor. He was once a member of the faculty of the University of Wisconsin Medical School. In 1939, Maine, New Jersey and Ohio passed similar statutes. In 1937 the California legislature passed such a law but it was pocket vetoed by the Governor. Other states have considered such a statute but for one reason or another have failed to pass it.

As indicated in the discussions in the law reviews and journals and by the decisions of the courts, the reliability of blood tests is being recognized more and more by our courts—both in states having blood test statutes and those having none. In New York—which has a statute—blood tests are always ordered when requested by the defendant. The corporation counsel of the City of New York, who prosecutes paternity cases, quite uniformly dismisses a case when blood tests definitely establish exclusion of paternity. He regards the law as very beneficial.

The attitude of the courts of other states is indicated by the following much cited cases:

Ohio: State ex rel. Slovak v. Halod, 24N.E.(2d)962 (1939); 63 Ohio Appeal 16.

Here the defendant was convicted in a bastardy proceeding although the blood tests definitely excluded him as a possible father. On appeal defendant contended that the verdict was against the weight of the evidence and that the trial court erred in refusing to instruct the jury as to the weight to be given to the results of the blood tests. If given, these instructions would have permitted the jury to decide the case on that evidence alone. In affirming the trial court's decision it was held that, since absolute conclusiveness and infallibility of blood grouping test results had not been definitely established, the court would not be justified in ruling that the test results in this case should nullify all the complainant's evidence to the contrary. Moreover, the court raises the point that a ruling to that effect would also have to presuppose absolute honesty and thorough competence on the part of the expert, and also the preclusion of all chances of innocent mistakes.

Pennsylvania: Commonwealth v. Zammerelli, 17 Pa. D.&C.229(1931). Defendant was tried on indictment for fornication and bastardy and was convicted though blood tests showed he could not be the father. A new trial was granted because the verdict was against the weight of the evidence.

California: Arais v. Kalensnikoff, 10Cal(2d)428; 74 Pac.(2d)1043(1937).

This was an illegitimacy case. Blood tests made by consent showed defendant could not be the father. He was seventy years old. The court found the defendant to be the father. The court of appeal reversed the lower court because the verdict was not supported by substantial evidence. Later the Supreme Court sustained the trial court holding that evidence of blood tests did not render other testimony superfluous, but since the scientific evidence and other evidence conflicted, the trial court must determine the relative weight of the two types of evidence.

Wisconsin: Euclid v. State 231 Wis. 616, 286 N.W. 3(1939). A blood test was ordered in a bastardy proceeding and the result showed the defendant could not be the father. Evidence of the test, however, was excluded, because not made in accordance with the statute.

The court said on page 620 (231 Wis.):

> In view of the several unsatisfactory and improbable aspects of the testimony, and in view of the positive exclusion of defendant by the blood test, however irregularly offered, we feel that in the interests of justice this case should be retried under circumstances that will give to plaintiff in error an opportunity to present in proper form medical conclusions based upon blood tests.

South Dakota: State v. Damm, 62S.D.123, 252N.W.7, 104A.L.R.430(1931).

Defendant was convicted on indictment for rape of an adopted daughter. Shortly before the trial closed, defendant offered to submit to a blood test and requested a blood test also for the child and its mother, which request was denied. On appeal the Supreme Court, speaking of the record in the case, said on page 446(104A.L.R.):

> We recapitulate the views hereinbefore set forth by saying that we think (1) the reliability of the blood test is universally conceded by competent scientific authorities; (2) a trial court of record in this state has inherent power and authority in its reviewable discretion, to order the taking of blood for such purposes in cases where paternity is an issue.

On rehearing in 1936, the Supreme Court said the reliability of the blood test was then universally conceded by competent scientific authority. The Court mentioned that the case was originally tried in 1931 and that practically all the literature on the subject was since that date, but by assistance of able counsel and its own investigations, the Court had arrived at a complete belief in such reliability. A new trial was refused because of the state of the record. Here the other evidence against the defendant was strong.

District of Columbia: Here the United States Court in 1940, according the *Journal of American Medical Association* of July 27, 1940, accepted as established the scientific value of blood grouping tests to the extent that they disprove paternity, basing its conclusion primarily on the report of the committee of that association on blood grouping tests, which report we have previously quoted.

These and other cases do not make blood tests conclusive but when performed by experts they are regarded as evidence of high probative value. The courts are ready to accept the reliability of blood tests within their limits when performed by known experts.

But these limits and the skill required in performing these tests present real problems. We have already pointed out that the committee of the American Medical Association reports that tests in the case of sub-groups *A* and *AB* are not sufficiently established for routine procedure and that group *AB* persons cannot be definitely excluded as parents of group *O* children.

Furthermore, medical men do not agree on how soon after birth reliable blood tests can be made. All medical men agree that *M* and *N* factors are present at birth, but there is disagreement as to when the *A-B* factors become fixed in a child. Many eminent authorities including Dr. Landsteiner and Dr. Wiener are positive in their conclusions that the *A-B* agglutinogens are fixed at birth, though the agglutinins do not become fixed until later, but that the agglutinins are not necessary for the tests and that reliable tests for *A-B* factors can be made immediately after birth.

However, Dr. Unger, one of the experts on the New York court list, states that in many cases these agglutinogens do not become fixed until a year or more after birth. Mr. Potter, Science Editor of the *American Weekly,* and Dr. Larson, a well known immunologist of our own university, are of the same opinion. Your committee believes that the weight of medical authority supports the view that the *A-B* factors are fixed at birth, but the disagreement among medical authorities on that point creates an uncertainty and dispute. This uncertainty should first be resolved by the medical profession—it should not be allowed to be carried into the courts for laymen to pass upon. If the tests are performed before the lapse of the period in dispute, it will greatly affect their reliability. If the trial is postponed for the purposes of these tests beyond the disputed time, it will mean a delay of eighteen months in counties having court only twice a year. This will greatly affect the practicability of the tests.

All authorities, including the law journals which strongly advocate the use of blood tests, are agreed that "the tests are rather difficult to make and expert skill is needed. If put into the hands of incompetent investigators disastrous results will follow." 2 Ohio State Law Review, 212 (May 1936). The higher the medical authority the greater is its insistence upon the need of a thoroughly competent expert.

Dr. Fishbein, editor of the *Journal of the American Medical Association,* in a response to a letter of this committee states:

It is hardly correct that "tests can be made for the *A, B, AB* and *O* groups by most hospitals and doctors." Only experienced serologists can reliably carry out and interpret such tests for medico-legal purposes. That holds true to a still greater extent for the determination of the blood types *M, N* and *MN.*

Although there are only fourteen experts on the court list in New York City, who are recommended by the Medical Society of that state as qualified to make these tests, some outstanding authorities contend that that very limited list is too inclusive and that there are only about three or four in New York City and one or two in the remainder of that state qualified to make such tests. When we consider that this list includes Dr. Landsteiner, who discovered the *A-B* and *M-N* factors, and Dr. Levine, who helped to discover the *M-N* factors, and Dr. Weiner, who is one of the greatest authorities on blood tests, we can appreciate the degree of skill required.

It is interesting to note that in Oregon, as recently as 1938 "only tests for *A-B* were made, since there are no facilities for testing for *M-N.*" 17 Oregon L. Rev. 203. These tests are made by Dr. Hunter of the University of Oregon Medical School.

In a very recent Wisconsin case, although a blood test statute has been in effect in that state for more than five years, an expert appointed by the court did not make the test for *M* and *N*, despite the fact that the test for *A-B* did not exclude the defendant as a possible father. The defendant was convicted and appealed to the Supreme Court, asserting as one of his grounds for a new trial the fact that he had been denied the right of a proper blood test. State v. Van Pappen 294 N.W. 560 (Nov. 8, 1940).

This Committee has given study to the availability in Minnesota of experts of unquestionable ability to perform these tests. Even many of the larger hospitals and clinics advise that they are not equipped to make tests for *M* and *N*. Others, including the Mayo Clinic, decline to make the tests for legal purposes. There is a readily understandable reluctance on the part of many to enter this field because it involves taking part in litigation and attendance in court takes experts away from their work. The test for *M* and *N* requires the greater skill. These tests have no value except to disprove paternity. The number of thoroughly qualified experts in Minnesota is very limited, due, no doubt, to the small demand for such tests. The Wisconsin statute contemplates several tests in some cases and the appointment of more than one but not to exceed three experts. This Committee is not convinced that there are a sufficient number of experts, willing to perform these tests, available in Minnesota whose ability would be unquestioned nor is it certain that the passage of the statute recommended would justify a sufficient interest to develop the technique required. It should, of course, be noted that the law provides for the cross examination of experts making the test. Securing the presence at the trial of such experts presents a difficulty, in expense at least, which should not be over-looked.

Your committee accordingly is of the following opinions:

1. That the results of blood tests within the limits herein outlined are reliable and when the uncertainties herein mentioned have been removed can be of great value in paternity cases,

(a) In discouraging the making of false accusations against innocent defendants.

(b) In causing a guilty defendant to admit paternity.

(c) In further reducing the possibility of convicting falsely accused persons.

(d) In rendering less uncertain the determination of fatherhood for illegitimate children.

2. That, because of the uncertainty of the availability of sufficient experts of the highest qualifications in this state, willing to perform these tests, and because of the difference of opinion as to when *A* and *B* factors become fixed in a child, it would be unwise to recommend the passing of such a law at this time, nor until there is a satisfactory answer to these problems; and that a blood test statute passed now might retard, rather than hasten, its beneficial use.

That, if and when a blood test law is passed, this Association should take a part in helping to determine what experts have the necessary qualifications and that only experts of unquestioned competency should be appointed.

4. That, if and when a blood test law is passed, it should make the cost payable by defendant. (Wisconsin alone provides for payment by the county and even there the Committee is informed the court often makes the order for the blood test conditioned upon payment of the costs by the defendant.)

5. That the place of the blood test in court should not be the addition of another item of evidence about which experts might argue and courts and juries disagree, but since it establishes, within certain limits, a biological fact which is undisputable, its use should be postponed until the uncertainties herein mentioned have been cleared away and until sufficient experts of unquestioned standing are available and willing to perform these tests.

In conclusion, it should be stated that this Committee, during its study, made effort to resolve the difference of opinion as to the fixation after birth of the *A* and *B* substances, but without success. It is hoped, however, that this study will, in a small measure at least, hasten the solution of the problems herein outlined and thereby help to make available an early beneficial use of blood tests in paternity cases.

Respectfully submitted,

MILTON I. HOLST,
County Attorney, Goodhue County,

International Falls, Minnesota.

THE SEROLOGY OF SYPHILIS AND ITS EVALUATION*

F. RYTZ
Minneapolis, Minnesota

THE diagnostic value of the serology of syphilis has always been controversial, not because the reactions are based on unsound immunologic principles, but mainly because of intricate biologic interference with the mechanisms of immunity, especially when in-vitro demonstrations are attempted. The various flocculation and complement fixation reactions are immunologically identical and depend upon specific antibody affinity for the antigen. Under certain circumstances, non-syphilitic elements in the patient's serum may unite with the cholesterol reinforced beef heart extracts usually employed as an antigen in the serodiagnosis of syphilis. In the serologic procedures in current use such nonspecific unity is indistinguishable from true syphilitic reactions. Several investigators[1,2,11] have obtained satisfactory sensitivity by employing a treponema pallida antigen in the Wassermann reaction, but the accuracy of the serodiagnosis of syphilis remained at the same unsatisfactory level as compared with the results obtained with the beef heart extract antigens in common use. The lipoid properties of the treponema pallidum appears to be similar to that of the tissue lipoid employed in the serology of syphilis since the lipoid of that organism constantly gives rise to a substance with affinity for the lipoid contained in alcoholic tissue extracts. The tissue extract reactions may, therefore, be conceived of as fundamentally specific manifestations.

In vivo experiments with flocculate of syphilitic rabbit serum, consisting of the antibody and the tissue lipoid combined, also indicate that the reinforced beef heart antigen is basically specific. Inoculations of such floccules are capable of inducing identical antibodies in animals of the same species.[7] The necessity of foreign protein in that mechanism, exemplified by inducing antibodies in rabbits to flocculate of human syphilitic serum suspended in saline,[7] is therefore ruled out since the formation of antibody with affinity for lipoid antigen is not dependent on the presence of protein or antibody from an animal of a different species. The fact that syphilitic serum under no circumstances by itself is capable of inducing antisyphilitic substances when intravenously injected, does not prove the absence of specific antibody. The physical state of the antigen is important in other forms of immunity as evidenced by the formation of antibodies such as anaphylactins, precipitins, and agglutinins where soluble and particulate antigens respectively are required for typical results.

Both syphilitic serum and the emulsion of tissue lipoid extract, when singly injected into rabbits, fail to induce an antibody with the capacity of reacting in vitro with beef heart lipoid antigen. On the other hand, when the emulsified lipoid is injected together with certain proteins of a different species, or if syphilitic antibody is attached to the lipoid emulsion particles, an antibody is formed when such material is intravenously injected into rabbits. The various routine tests for syphilis show positive reactions when applied to the serum of the inoculated animals, but the differential test described by the author[8,9] classifies such reactions as nonsyphilitic manifestations. When flocculate of positive differential tests, obtained in patients with clinical syphilis, is inoculated intravenously into rabbits, the animals develop both positive routine tests for syphilis and positive differential reactions. These facts illustrate to some extent the nature of both specific and nonspecific serologic tests for syphilis and point to the serum protein as a source of false positive reactions.

Cause and Extent of Nonspecific Syphilis Tests

Certain serologic similarities present themselves in syphilitic and in tuberculous infections. In the serology of tuberculosis, the x-ray and cutaneous tests have revealed flaws both in regard to specificity and to sensitivity. It is now generally agreed among numerous investigators that complement fixation methods in the serodiagnosis of tuberculosis show false positive reactions to the extent of from 15 to 20 per cent, and that such reactions fail to detect the infection in about

*From the Section of Serology, Clinical Laboratories, Minneapolis General Hospital, Minneapolis, Minnesota.

30 per cent of all tuberculous patients tested. In syphilitic infection, the most sensitive flocculation methods in the serodiagnosis of that disease exhibit greater sensitivity and are capable of detecting about 95 per cent of syphilitic infections. According to the latest conceptions of specificity in the serology of syphilis, we are, most likely, not much nearer reality than in the case of tuberculosis. Lately, official serologic evaluation committees have contributed greatly to the uncovering of weak links in the serology of syphilis. The several serologic methods in more or less general use vary greatly in sensitivity and in simplicity of performance, but to establish the difference in specificity when the various tests are applied to all types of disease, becomes a hair-splitting and insignificant proposition in comparison with the greater number of false positive reactions by all tests.

Possible fundamental causes of false positive reactions in the serology of syphilis have been discussed in a previous publication.[9] The various protein fractions, according to Sörensen,[6] are unstable and transmutable entities. Under certain circumstances, albumin may be transformed into globulin, part of which appears closely related to antibody, and the affinity of both factors for cholesterol reinforced lipoid antigen appears to be increased by heating the serum at 56°C. or at a higher temperature. Infectious diseases other than syphilis may in various ways influence the normal relation between the different fractions of the serum protein and thereby increase the liability of false positive serologic reactions. It has been shown that bacterial contamination of the serum samples may cause nonspecific syphilis tests.[8] Most likely, certain forms of nonsyphilitic infection produce antisubstances with affinity for the antigen of syphilis tests.

The League of Nation's health organization[4] has pointed out a number of nonsyphilitic conditions which may cause false positive syphilis tests, and Krag[3] has demonstrated strong reactions in a number of nonsyphilitic diseases. The following disorders may be listed as possible causes of nonspecific syphilis reactions: leprosy, malaria, infectious mononucleosis, tuberculosis, scabies, psoriasis, acne, Vincent's angina, measles, pneumonia, bronchitis, cerebral hemorrhage, epilepsy, rat-bite fever, respiratory infections, lead poisoning, pregnancy, bone fracture, headache, diabetis, et cetera. In absolute health, especially in young individuals, false positive syphilis reactions are seldom observed.

There are strong indications that the arsenical compounds used in the treatment of syphilis contribute to misleading serologic findings. It is common knowledge in the field of serology that certain patients, treated for a long period of time, become "Wassermann-fast" at the point of weakly positive serologic tests and show negative reactions after discontinuation of the treatment; in some treated syphilitics, the serology remains positive indefinitely. It has been observed by this author that a considerable number of individuals, classified as having latent syphilis on the strength of positive routine tests, are several years later designated as being in a serology-fast state. In such cases, the differential test is usually found negative.

In the presence of tertiary syphilitic lesions, the cause of negative syphilis tests may possibly be found in antibody absorption by antigenic material of the blood stream. In cases with syphilitic aneurysm, routine tests have been found negative although post mortem examinations have revealed active syphilitic lesions. In those instances, the differential test has been positive. In cardiac cases, the blood sample for the differential reaction should be drawn before the administration of digitalis since that substance seems to interfere with the protein-antibody relation to the copper sulphate employed in that method and this may cause false negative reaction. The ingestion of alcohol by syphilitic individuals has the same effect, especially in individuals with neurosyphilis.

The relation between the antibody of the serum and that of the spinal fluid in individuals with neurosyphilis has been discussed in a publication now in press.[9] It appears that in certain cases with that form of syphilitic infection, degenerated cell material may pass from the spinal canal to the blood stream and cause positive blood reaction of the same nature and by a similar mechanism as the reactions induced by species specific flocculate in the rabbit.[7] On that basis it would be explainable why some neurosyphilitic patients without the involvement of other organs fail to show positive blood tests at that stage of the infection. For some obscure reason, immune substances may in such cases fail to reach the blood stream. It would seem improbable that negative blood reactions in patients with neurosyph-

ilis could be due to the absorption by antigenic material from the spinal canal as long as the spinal fluid shows positive serologic tests for syphilis.

er or longer periods of time. The technic was adjusted accordingly by sensitizing the alcoholic beef heart extract antigens by the addition of another lipoid in the form of cholesterol. Other

Variation in Serologic Procedure

The Wassermann reaction, based on complex immunologic factors, has been the nucleus around which other serologic methods in the serology of syphilis have developed. For the standardization of the complement fixation method, the clinical diagnosis has served as a sound basis. But it was soon observed that the Wassermann test failed to show positive reactions in some cases with both a history and clinical findings of syphilitic infection, especially in patients given anti-syphilitic treatment for short-

sensitization efforts, such as ice box incubation, were attempted with some success. At the same time, doubt was cast on some of the positive results obtained by the changed technic, and the lack of sensitivity during the early period of treatment became an established fact. In attempting to increase the diagnostic value, modifications of the Wassermann reaction became innumerable, but none of the procedures were capable of doing justice to either the patient or the physician.

The flocculation methods constitute simpler and more direct methods of testing, and, as point-

ed out above, the most sensitive of these procedures leave but small percentage unrecognized of syphilitic individuals tested. On the other hand, the number of false positive tests are relatively large both by the flocculation and the complement fixation method. The former procedure appears to show more post-cure positive reactions due to the influence of arsenical compounds on the stability of the serum protein as evidenced by the number of serology-fast cases and by the results obtained by the differential test after elimination of the serum protein.

Aside from certain fundamental immunologic principles, general rules are few or nonexistent in the design of serologic procedure. A standard antigen, for example, to be used in the different methods of testing for syphilitic infection, appears to be an impossibility. If one factor of the technic is changed, other phases must be adjusted accordingly. However, in considering technical details of the various methods, one common aspect appears discernible; a sensitive, and at the same time rapid method, must take into its service some form of physical force, such as shaking or centrifugation, in the process of antigen-antibody combination, in order to avoid employment of a hypersensitive antigen which in turn will result in an excess of false positive reactions. If the sensitivity factor of a rapid test depends entirely on the antigen, nonspecific reactions will be too conspicuous. Some of the sensitive, rapid slide methods will illustrate that point. In absolute health such methods may or may not be found reliable in comparison with other tests, but if applied to the various forms of disease encountered in routine work, those procedures will prove unsatisfactory. The post-cure positive serologic tests appear to be excessive. If the time element of performance is left out of consideration, a moderately sensitive antigen may serve a sensitive method without showing excessive numbers of nonspecific reactions.

Unsatisfactory Antigen as a Source of Misleading Serologic Reactions

In obtaining satisfactory results in the serodiagnosis of syphilis, the preparation of the antigen is of great importance. The technicalities involved in the preparatory measures are as practicable as any phase of the test itself and should preferably be managed by the individual laboratory since the age of the antigen is significant. The Rytz antigens[8,10] are not fully satisfactory for more than six months after the date of preparation. The age of the beef heart powder employed also plays a major rôle in the quality of the finished antigen. If such material has been kept in stock for many months before extraction, the final product will prove to be of inferior quality. The cholesterol crystals should be tightly sealed and kept in ice box temperature until dissolved in absolute ethyl alcohol. In solution, the cholesterol will remain stable for an indefinite period of time. If the antigen has lost its potency or titer due to too long storage, the lost qualities are irrestorable and the antigen will tend to give both false positive and false negative reactions in the same manner as an antigen designed for a certain method will prove unreliable in other procedures.

Although it is desirable for satisfactory results that the individual laboratory prepare the antigen for the serologic tests employed, it cannot be anticipated that such efforts will be general in the near future. As a step toward more uniform results in the performance of routine presumptive tests for syphilis, it would seem practicable that the public health laboratories of the various states, in collaboration with the authors of the tests currently used, manufacture and distribute the antigen required in public and private laboratories in the respective districts. In connection with standing state serologic evaluation committees, such a measure would be another constructive step toward more uniformity of the results in routine serology.

Method of Differentiating Between Specific and False Positive Syphilis Tests

There are strong indications, as pointed out above, that the various factors of protein liability constitute the main cause of misleading results in the serology of syphilis. By the methods ordinarily employed in precipitating serum globulin, the antibody of immune serum is also removed or rendered serologically impotent by the chemicals used in strong solution. It has been demonstrated[8,9] that a highly diluted copper sulphate, such as a 2 per cent solution when employed as a precipitant, leaves the reacting substance of syphilitic serum in solution while the bulk of serum protein is removed by precipitation. The total amount of protein or protein-like substances left in solution ranges from approx-

imately 100 to 250 mg. per 100 c.c. of supernatant fluid as estimated by the ordinary quantitative tests for serum protein. If a few serum samples from syphilitic and nonsyphilitic individuals are separately pooled and the serum protein precipitated by a 2 per cent copper sulphate solution, the diluted[8] supernatant fluid of the syphilitic serum will uniformly show a higher protein content than the pooled serum from nonsyphilitics. On the other hand, if serum samples from syphilitic patients are singularly tested by the same method, an occasional serum will show a supernatant fluid with a protein content as low as 50 to 100 mg. per 100 c.c., which is the average amount of protein in the supernatant fluid of normal serum. However, the amount of protein left in solution has no bearing on the differential reaction. The specific reacting substance of syphilitic serum apparently unites with the copper sulphate of the supernatant fluid and thus is available in sensitized form for a properly adjusted serologic flocculation method.[9]

The results obtained by the differential test in syphilitic rabbits and in animals showing false positive syphilis reactions, and also the findings by that method in comparatively large groups of human beings, have been described.[8,9] The differential test was privately applied to samples recently submitted to this laboratory by the Minnesota state serologic evaluation committee.[5] Of ninety-nine blood samples from patients with a clinical diagnosis of syphilis or from patients with positive routine presumptive tests for that disease, seventy proved to have positive differential tests. That group had been treated on an average of one and one-half years; of the remaining twenty-nine blood samples from presumably syphilitic donors, twenty had been treated averagely for two and one-half years and showed more or less positive routine Rytz and Kahn reactions, but the differential tests were negative as indicated in Table III. The remaining nine donors had negative routine Rytz and Kahn reactions and the differential test was therefore not applied.

In 3,100 individuals presenting themselves as blood donors, thirty-two were found to have positive routine Rytz and Kahn reactions; twenty-five of that group showed positive differential tests, and the majority gave a history of primary or secondary syphilitic lesions. The seven cases

3100	32	1	25	7*	22

*The donors with negative differential tests had no history of syphilitic infection and were also found to be without clinical symptoms of that disease. The routine serology in that group was weakly positive.

with negative differential tests had weakly positive routine Rytz and Kahn reactions and none revealed a syphilitic history.

Comment

The "routine" tests commonly used in the detection of syphilitic infection may continue to serve as valuable and simple presumptive measures in connection with more exacting diagnostic reactions in the form of differential or verification tests. The differential test described by this author[8,9] should not be conceived of as a single, sure instrument in the serodiagnosis of syphilis. Its application is intended only in case the presumptive reactions are positive or in the few instances where such tests are negative and the clinical picture is indicative of syphilis. The wider use of the differential reaction is partly prevented by the fact that it requires clear serum, free of hemoglobin or other excessive pigmentations. As pointed out above, it is equally important that the patient has not been under the influence of alcohol for several days prior to the blood examination, and that digitalis has not been administered.

In consideration of recent developments in the serology of syphilis and the increasing cautiousness among clinicians, the future serodiagnosis of syphilis will undoubtedly call for considerably more time than the past has allotted for that purpose. The newer form of serology requires repeated and continuous laboratory study for shorter or longer periods of time depending on the clinical findings. From a serologic point of view, the first blood sample may not be found satisfactory. Neither the result of the routine tests nor the differential reaction should be definitely interpreted on the basis of a single examination.

The reports of official serologic evaluation committees indicate that serologic technic in the average clinical laboratory as yet is in the process of development. The serologic laboratory of the near future will undoubtedly demand more thorough training of its technical workers in order to meet new and exacting demands in connection with the general campaign against syphilis. It is in the interest of social security that that infection and similar diseases are arrested, but it is in the interest of social justice that as few as possible are subjected to a hasty and incorrect diagnosis based on misleading serologic findings. Serologic reactions and the "human element" of performance can never be perfect, but the responsible serologist must at least possess the same degree of infallibility as the originator of the test which he is performing. Differential and verification tests may still be in the experimental stage, but on the basis of the results obtained in several thousand cases, there is fair reason for the clinician in charge to withhold a final diagnosis of latent syphilis in cases with negative differential tests and no other indication of the infection than a positive "routine" serologic test for syphilis.

Summary

The fundamental principles of the serology of syphilis have been discussed and it has been pointed out that the use of spirochetal antigen in the serodiagnosis of syphilis is no safeguard against the occurrence of false positive reactions. The cause of nonspecific reactions appears traceable to the unstable nature of the various fractions of the serum protein. In certain cases, the arsenical compounds employed in the treatment of syphilitic infection seem to contribute to the general unreliability of routine tests in the serodiagnosis of that disease.

The difference in reliability of the various routine tests for syphilis appears to be relatively slight in comparison with the general unreliability of all the so-called routine tests.

In employing the differential test in all cases with positive routine or presumptive reactions, the final interpretation of the serodiagnosis of syphilis appears to be in closer harmony with the clinical findings.

MARIE'S HEREDITARY CEREBELLAR ATAXIA (OLIVOPONTOCEREBELLAR ATROPHY)*

ROYAL C. GRAY, M.D., Ph.D.
and
CLARENCE P. OLIVER, Ph.D.
Minneapolis, Minnesota

HEREDITARY ataxia was first described by Friedreich[10] in 1861 at the congress of German naturalists and physicians at Speyer. Two years later he further set forth the disorder in an account of six cases in two families affected with a "degenerative atrophy of the spinal posterior columns," stated it was a new disease, and distinct from the usual type of Duchenne's locomotor ataxy. In 1876 he gave the condition the name of "hereditary ataxia." Nevertheless all other writers of those times considered it as a hereditary or juvenile form of tabes, or of multiple sclerosis, or a combination of the two. Finally in 1882 Brousse[5] agreed that hereditary ataxia was an entity and proposed the term "Friedreich's ataxia." Since then Friedreich's ataxia (hereditary spinal ataxia) has been established as a degenerative heredofamilial disease involving the nuclei dorsalis (Clarke's columns), the posterior and lateral columns of the spinal cord, and the posterior rootlets. The classical clinical syndrome customarily appears before puberty and includes ataxia of skeletal musculatures, nystagmus, kyphoscoliosis, and foot deformity.

Considerable variation in symptoms occurs between different families affected with Friedreich's ataxia. A particular family disease type (genotype) is said to characterize the condition. However, variations also appear between different members of any affected family. Intermediate, incomplete, aberrant, or transitional forms of hereditary ataxia have long been recognized. The classical syndrome of Friedreich's disease thus may veer toward any one of the various myelopathic, neurotic, or myopathic hereditary conditions. A clinical and pathological study of Friedreich's ataxia reported by Baker[1] showed spinal cord, peripheral nerve, and skeletal muscle degeneration all in one patient.

In 1893 Marie[15] reviewed sixteen cases in which the symptoms he thought did not exactly belong in the Friedreich's ataxia entity. Necropsy data were present in only two of these cases. This new clinical syndrome, which he ascribed to a congenital defect or arrest of development of the cerebellum, Marie termed "hereditary cerebellar ataxia."

Marie's concept was evolved from these sixteen "abnormal cases" of Friedreich's ataxia noteworthy among which was the report by Brown[6] in 1892. This latter report concerned twenty-one affected members of a family over five generations with age of onset from sixteen to thirty-five years. These patients showed clinical signs of cranial nerve involvement such as Argyll Robertson pupils, optic atrophy, ptosis, and diplopia. They did not have nystagmus or foot deformity. Pathologically there were morbid changes in the cerebellum which were restricted largely to the Purkinje cells and olivary bodies. Also, as in Friedreich's ataxia, in the spinal cord the posterior columns, Clarke's columns (nuclei dorsalis), and Flechsig's (dorsal) direct spinocerebellar tracts were markedly involved and the pyramidal tracts were slightly involved.

Although he created the term "hereditary cerebellar ataxia," Marie conceded transitional forms between that disorder and Friedreich's ataxia could occur and thus the one or the other affection might be different modalities of the same morbid process. Wilson[19] states that claim to clinical independence for Marie's hereditary cerebellar ataxia rests upon its onset in adult years and consequently more definite hereditary character (as opposed to early onset and familial aspects in Friedreich's ataxia), persistence or exaggeration of deep reflexes (as contrasted to their decrease or loss in Friedreich's ataxia), and frequently associated optic atrophy and ocular paresis.

In 1900 Dejerine and Thomas[9] described the pathology in a degenerative disorder which they named olivopontocerebellar atrophy but they said

*From the Division of Nervous and Mental Diseases, University of Minnesota Medical School and the Department of Zoology, University of Minnesota.

it was neither a familial nor a hereditary condition. Holmes[12] in 1907 described a form of familial degeneration of the cerebellum and asserted that a majority of cases of progressive cerebellar disease belongs to the class of olivopontocerebellar atrophy. The pathological report in his paper was based upon the examination of the central nervous system of one of four siblings affected in this particular family. Grossly, the cerebellum, pons, and medulla were very atrophic. Microscopically, the specimen showed atrophy and outfall of Purkinje cells, rarefaction and reduction of the molecular and granular layers, some degeneration of fibers in the folia and central white matter, sclerosis of the inferior olives, and disappearance of the olivocerebellar tracts. It did not show any involvement of the pontile nuclei or pontocerebellar contingents. Holmes'[12] case therefore represents, strictly speaking, olivocerebellar atrophy which, however, is probably only an incomplete form of olivopontocerebellar atrophy.

Davison and Wechsler[8] held that olivopontocerebellar atrophy may be differentiated from Marie's hereditary cerebellar ataxia both clinically and histologically. They said the hereditary or familial character is more constant in the ataxia, while the ocular manifestations, such as optic atrophy and ocular palsies, are more common in the atrophy group. They also said although there is destruction of the Purkinje cells in the ataxia, the moss and climbing fibers (cerebellipetal elements) may be spared whereas in the atrophy group the olives, pons, and cerebellum together with its various cerebellipetal elements are all more or less affected, while the Purkinje cells, and inferentially the cerebellifugal elements, are only affected in the later stages of the atrophy. These authors reported an illustrative case of olivopontocerebellar atrophy with the additional involvement of the dentate nuclei and also the unusual associated phenomenon of involvement of cranial nerve nuclei, namely, the right third to tenth inclusive.

However, Hassin and Harris[11] are authority for the now generally accepted opinion that Marie's hereditary cerebellar ataxia and olivopontocerebellar atrophy are one and the same disease process. The atrophy was shown to be a heredofamilial degeneration by these authors, by Keiller,[13] and by Yang et al.[20] Waggoner and co-workers[18] reported a case of hereditary cerebellar ataxia and a genetic study of the individual's family. Dejerine and Thomas[9] forty years ago first described the principal and still recognized pathological features of olivopontocerebellar atrophy as including atrophy of the cerebellar cortex, bulbar olives and pontile gray matter, degeneration of the middle cerebellar peduncles (brachia pontis) and of the inferior cerebellar peduncles (corpora restiforme) with relative integrity of the central nuclei (dentate and other cerebellar roof nuclei, emboliformis, tecti and globosus). The clinical syndrome is clearly and characteristically cerebellar in nature, with onset in adult life. Occasional symptoms, incompatible with only olivary, pontile, or cerebellar pathology, are (1) urinary disturbances such as retention, automatic bladder, and incontinence which might arise from destruction of the visceral afferent ganglion cells in Clarke's columns (nuclei dorsalis) of the spinal cord, and (2) psychical symptoms such as impairment of sensorium and intellect indicating cerebral involvement.

The most common types of degeneration of the cerebellum are olivopontocerebellar atrophy and parenchymatous cortical cerebellar atrophy. In the former the atrophic degenerative changes are in the medullary (bulbar) olives, the basal (ventral) portion of the pons, and the white substance of the cerebellar lamellae. The tract degeneration involves the afferent fibres of the cerebellum (cerebellipetal fibers). The changes in the cerebellum are secondary to those in the medulla and pons. The ganglion cells of the cerebellar cortex may be spared or there may be transsynaptic degeneration of the cortex. In parenchymatous cortical cerebellar atrophy the primary changes are in the ganglion cells of the granular layer (Purkinje, granular, basket, and large and small stellate cells) and the degeneration involves their axones. The degeneration of the Purkinje cell efferent (cerebellifugal) axones causes transsynaptic degeneration of the cells in the dentate nuclei which in turn affects the other cerebellifugal tracts and produces atrophy of the superior cerebellar peduncles (brachia conjunctivum). Thus the process may extend to the nuclei ruber in the midbrain and even beyond to the thalamus and cerebral cortex. The loss of the cell bodies in the granular layer and their dendritic processes in the molecular layer is the basis of parenchymatous cortical cerebellar atrophy. Richter[17] reported a familial instance of

parenchymatous cortical cerebellar atrophy in which the ratio of the weight of the cerebellum and brain stem (130 grams) to the total brain weight was 1:19, whereas normally the ratio is 1:6 or 1:7 (normal cerebellum and brain stem weight 155 to 180 grams). However, as shown by Kirschbaum and Eichholz,[14] there is not always gross atrophy of the olives and cerebellum. Histological examination is the only certain method of proof of this degenerative disorder. According to Parker and Kernohan[16] the onset is generally in the later adult years and in their review of twelve cases there was no history of familial incidence.

In summary, it is now recognized that there are many variants of spinal and cerebellar ataxia incident to heredofamilial degenerations. The degenerations are primary, and variously referred to as an abiotrophy (Gowers), a premature senescence (Raymond), a pathoklyse (Vogt), or a defect of vital endurance. No etiological factor other than a genetic error has been demonstrated. There are three fairly distinct clinical and pathological entities, namely, Friedreich's ataxia (hereditary spinal ataxia), Marie's hereditary cerebellar ataxia (olivopontocerebellar atrophy), and parenchymatous cortical cerebellar atrophy. The individual and his family reported in this paper illustrate the classical hereditary, clinical, and pathological characteristics of Marie's cerebellar ataxia (olivopontocerebellar atrophy).

Case Report

B. W. S., U. H. No. 631249, whose position in this family is indicated by the arrow in generation IV of the genealogical chart (Fig. 1), was examined in September, 1934. He was twenty-five years old, single, and employed on his mother's farm. Her health had always been good. His father died in 1918, at the age of thirty-three years, the cause of death being given as locomotor ataxia. His paternal great-grandfather, paternal grandmother, three paternal uncles, three paternal aunts, and four cousins died of a similar neurological disorder. His oldest sister, four cousins, and one second cousin were currently likewise affected and four other cousins probably affected.

His medical history except for his presenting complaints was negative. He was a total abstainer from tobacco and alcohol. He graduated from the eighth grade, country school, at the age of thirteen years and thereafter continued to live and work on the home farm. However, a slowly progressive ataxia was gradually incapacitating him and therefore, in company with several of his cousins, some of whom were similarly affected and others not affected, he came to the University of Minnesota Hospitals for diagnosis and medical attention.

About five years previously he first noticed difficulty in walking, writing, and talking. Locomotion was particularly troublesome in the dark; if he closed his eyes he would have to shuffle and grope his way. His writing was becoming laborious and rather illegible. He could not button his clothes easily. He was unable to play ball as he once did since he could not run or judge direction or distance correctly in throwing the ball. He had developed some apparent prominence of his eyeballs but his vision was unimpaired. There were no symptoms or signs of any type of aphasia. He spoke with some hesitancy and the words would tend to run together, to be indistinct or slurred. He felt well in all respects except as incident to the ataxia. His difficulties varied somewhat, some days being worse than others.

Physical Examination.—The patient had a medium figure and medium frame. His temperature was 98.6 degrees F.; pulse 86; blood pressure 128/80; height 70 inches; weight 144 pounds. His eyes had a peculiar staring expression. The frontalis muscles were kept more or less contracted, thereby raising the eyebrows and secondarily the upper eyelids, causing widened lid slits and the appearance of exophthalmus. The routine physical examination was otherwise negative.

Neurological Examination.—The cranial nerves were all normal. The deep reflexes were uniformly increased, 2 plus, and were bilaterally equal. The superficial reflexes and the toe reflexes were normal and there was no clonus. The motor system was normal throughout except as noted in the following paragraph.

The standard finger to finger and finger to nose tests showed definite incoördination. These tests also demonstrated bilaterally a certain degree of asynergia, dysmetria, and cerebellar hypotonus. Asthenia and slowness in muscular contractions and the rebound phenomenon were present and finer movements in general were incoördinate. There was no localizing unilateral cerebellar phenomena such as dysdiadokokinesia, spontaneous deviation, or past pointing. Heel to knee tests showed considerable incoördination bilaterally, somewhat more marked on the left. Asynergia, dysmetria, and cerebellar hypotonus were as evident in the lower as in the upper extremities. Romberg test was positive and the patient's gait was decidedly ataxic.

All forms of superficial and deep sensibility were normal. There was no vasomotor or trophic disturbance. Dysarthria was noticeable; his speech tended to be indistinct as in bulbar or pseudobulbar paralysis. His handwriting was manifestly incoördinate.

Mental status was normal other than for the patient's lack of any great concern about such an obvious disability as he had at the time and the inescapable outcome of the disorder which he knew had been the lot of so many members of his family who had been similarly affected. It was not the attitude of resignation or laissez faire or of well being in the face of

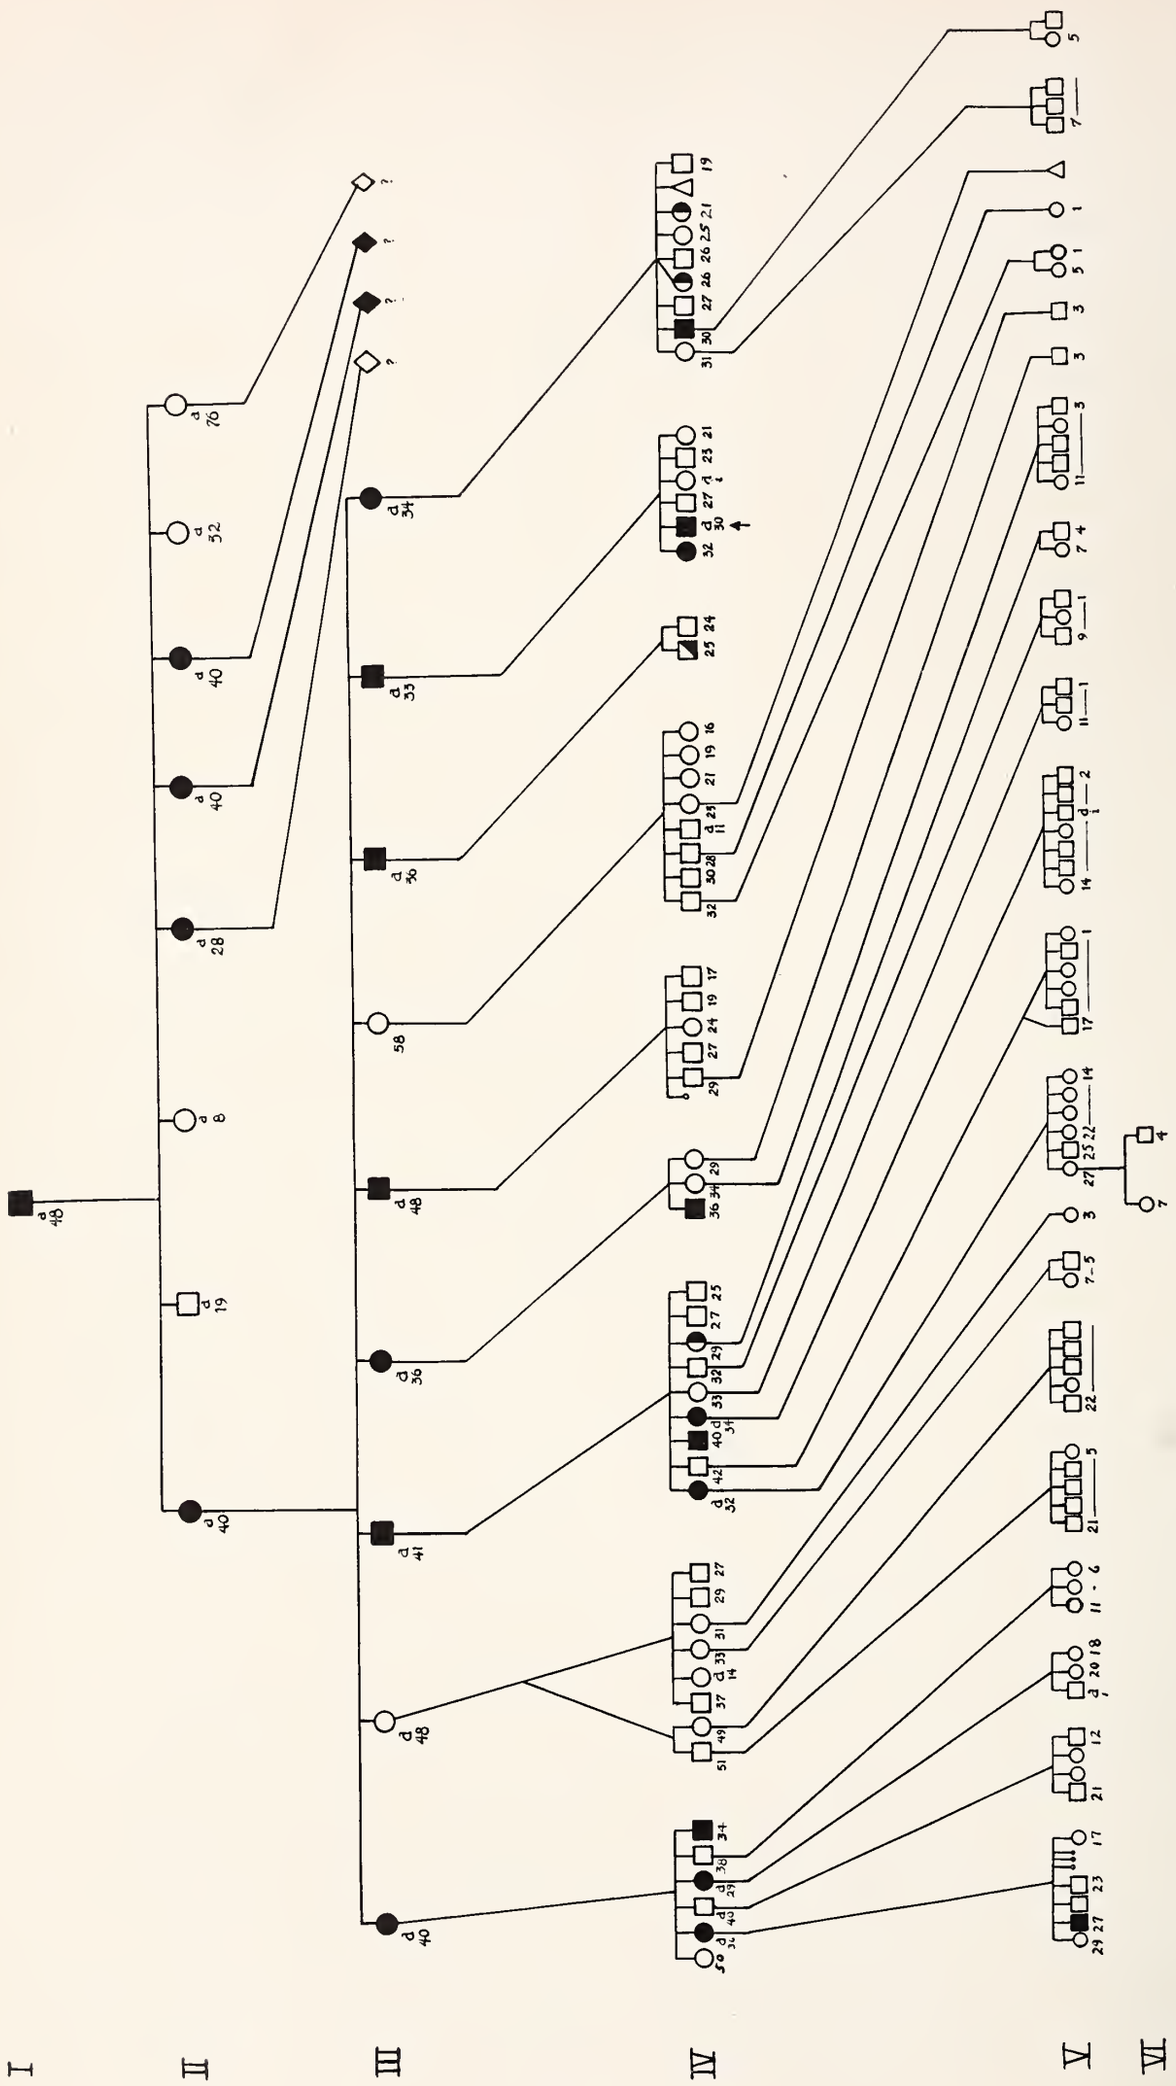

Fig. 1. Genealogical chart of the six generations studied for ataxia. Necropsy in generation IV indicated by arrow. Symbols: ataxic members, solid squares for males and solid circles for females; questionable cases, half solid; generations, Roman numerals; ages in 1939, Arabic numerals, with "d" to indicate death; diamond, families on which data are incomplete.

structural ill health; rather, it seemed to be a dullness of emotion and insight.

Laboratory Examinations.—Urinalysis was negative. The hemoglobin was 78 per cent, leukocytes 7,200 per cu. mm. with neutrophiles 79 and lymphocytes 21 per cent. The blood Wassermann was negative. The basal metabolic rate was plus 11 per cent. The spinal fluid

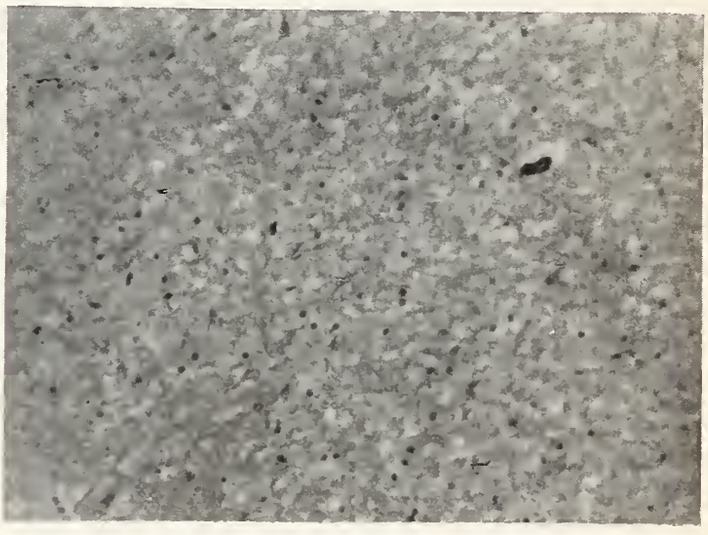

Fig. 3. Brachium pontis. Partial demyelinization and vacuolization. Hemotoxylin-eosin stain. X 300.

was clear and colorless, pressure 8 mm. of mercury, Queckenstedt test produced a rise to 12 mm. on the left and 14 mm. on the right with a prompt return to 8 mm. on either side, cells none, Nonne negative, Wassermann negative, colloidal gold curve 1221111111.

A diagnosis of Marie's hereditary cerebellar ataxia (olivopontocerebellar atrophy) was made on the purely cerebellar neurological findings, the onset in adult life, and the definite hereditary character of the disorder.

Following his hospital study the patient returned o his home and continued with his farm work. The ataxia and attendant disability gradually progressed. He became bedridden about three months before his death in March, 1939. The terminal condition was reported as being bulbar in nature with laryngeal paralysis, difficulty in breathing and finally bronchopneumonia.

Necropsy Report.—Gross examination of the brain revealed the external surface to be essentially negative. The cerebellum appeared to be somewhat decreased in size. The olives were flattened and much smaller than normal. This was especially so on the right where only an irregular shriveled protuberance marked the location of that structure.

All the microscopic sections were stained with hemotoxlyn-eosin, azocarmine, Bielschowsky's silver, and Weigert's myelin sheath stains.

Sections of the cerebral hemispheres and midbrain and peduncles showed no abnormality. The cortical cells were intact. There was no apparent involvement of any part of these structures.

Sections of the cerebellum showed a diffuse but patchy lamellar degeneration of the white substance. There was a severe destruction of fibers in some areas with a relative increase of glial cells. The white substance in those areas had almost a vacuolated appearance.

Sections of the cerebellum revealed primarily an extensive disappearance of the Purkinje cells (Fig. 2). An estimated two-thirds of these cells had disappeared leaving only about one cell per low power field. Only a few of the cells that did remain had any resemblance to the normal. The cell bodies showed two types of change. Some cells contained pyknotic irregular nuclei, the cell bodies proper being hypochromatic and somewhat shrunken. The other type of change was a loss of tinctorial properties. The cells were moderately swollen, stained very lightly, were usually rounded, and contained no neuclei or at most only small fragments of nuclear tissue. Many of these cells had become shrunken and frayed while others had continued to lose their staining properties and now appeared as very faint outlines of the original structures and could easily be called "ghost cells." The cell processes were few and fragmented. Rarely was a cell seen which had dendritic processes and if so its ramifications within the molecular layer were sparse. Generally those cells whose dendritic processes were still present also had intact nuclei although often their outlines were quite faint and difficult to discern. The granular layer of the cerebellum otherwise appeared to be uninvolved.

Sections through the dentate nuclei indicated that structure had almost disappeared. Only an occasional degenerating nerve cell remained. Those cells were fragmented, hypochromatic, and had few or no cell processes. In some areas there were no cells seen in the location of the dentate nucleus.

Sections through the upper pons showed an almost complete destruction of olivocerebellar fibers, only a few strands of fibers being still visible. Other sections of the pons showed a considerable demyelinization and vacuolization of the brachia conjunctivum (superior cerebellar peduncles) with a lesser involvment of the

brachia pontis (middle cerebellar peduncles) and corpora restiforme (inferior cerebellar peduncles). This is illustrated in Figure 3. The pyramidal system as well as the trapezoid body and lemnisci were intact.

Sections through the upper medulla showed a striking destruction of cells in the olives (Fig. 4). The few cells which they did contain were mostly abnormal in

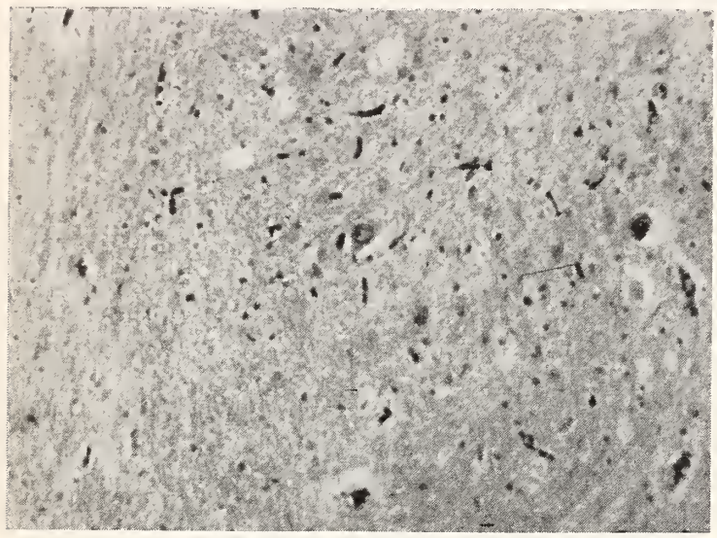

Fig. 4. Medullary olive. Destruction and paucity of nerve celis. Hemotoxylin-eosin stain. X 300.

structure. They showed a fragmentation, shrinking, and loss of tinctorial properties with injury or disappearance of their nuclei and conversion into "ghost cells." Within the hilus of the olives only an occasional fiber was seen. The destruction of the olives was about equal bilaterally.

Sections of the cervical spinal cord showed no involvement of any of the fiber tracts or nerve cells in that portion of the cord and hence, inferentially, there was no involvement in the cord below that level.

Genetics of the Ataxia

A study of the history of ataxia in this family indicates that heredity is involved. Although the severity of the ataxia may be influenced by other circumstances, the actual appearance of the disease in each member seems to depend upon a hereditary basis. The trait has appeared in some members in each of five generations of the family, and has not developed in any person who married into that family.

Genealogy.—The transmission of the ataxia in this family is shown by the accompanying chart (Fig. 1) for which the data have been checked against several sources of information from the family. In the chart, the solid squares represent affected males; the solid circles, affected females. Half-solid squares and circles represent questionable cases. Only the immediate members of the family are shown. Roman numerals indicate the generations. Arabic numerals, given below the individuals, indicate the ages of the members in 1939. In the fifth generation the ages between the lowest and highest are in part omitted. The symbol "d" with a numeral indicates the age at death. A triangle is used for an individual whose sex is unknown; a diamond with "?" for a line of descendants for which data are not complete. Small circles represent stillbirths.

Type of Heredity.—The ataxia seems to be inherited as a Mendelian dominant. Sex-linkage apparently is not involved, since the trait has passed from a father in generation III to a son in the third and also in the eighth families of generation IV. In order to assume that the trait is recessive, sex-linked or Mendelian, it would be necessary to assume that the many individuals who married into the family were carriers, heterozygous, for the trait. The ataxia occurs too infrequently in the general population for such a condition to be true, although Brain[4] and Blacker[2] assume that a common recessive gene acts with a mutant dominant gene for the development of ataxia. The appearance of the trait is not limited or influenced by sex, although, as will be mentioned, the severity may be greater in the female. Of the twenty-three definite cases in the family, twelve occurred in females and eleven in males.

All the data fit the interpretation that in this family the trait is similar to many cases reported, and behaves as a simple Mendelian dominant. Each affected member had one affected parent. The second and sixth members of generation III were not affected and, as is to be expected on the basis of dominance, their children are normal for the trait. Ten or possibly thirteen of the offspring in these two families are of an age at which the symptoms could be recognized. In the case history reported by Brown[6] normal parents do produce affected offspring.

On the basis of dominance, since each ataxic member married a person who was not affected, one-half of his progeny should be affected. Owing to the variations in the age of onset, it is not possible to determine accurately the frequency with which the trait appears. The age of the youngest affected member of the family is twenty-seven years. If his is taken as the crucial age for a definite recognition of the trait and all members who have not reached that age are omitted from the count, the family chart shows that twenty children of ataxic parents are not affected; twenty-two are ataxic; and one is questionable. The observed frequency, 53 per cent, closely approaches the 50 per cent expected. The age of the youngest questionable case in the family is twenty-one years. On the basis of this age, thirty-one children of ataxic parents are not affected, twenty-two are affected, and four are questionable. This frequency, 46 per cent, does not differ greatly from that expected.

In the second generation, four of the six children who lived to the probable age of onset were ataxic. In the third generation, seven of the nine members in the sibship were ataxic. Twenty-five members in generation IV have reached the age of twenty-seven years; ten of these are recorded as ataxic, one as questionable, and fourteen as not affected. Thirteen other children are older than twenty years; three of these are classified as questionable, and ten as not affected. Only three of the fifth generation have reached twenty-seven years, and one of these is ataxic. Four other non-affected members have reached twenty-one years.

Age of Onset.—The ages of onset of the disease are not known for many of the cases. The two cases known in generation III occurred at twenty-one and at thirty-three years. In generation IV, the onset for seven cases (four known for certain) has ranged from ages twenty-one to thirty, with an average age of twenty-four years. The one affected person in generation V developed symptoms at twenty years. In this family, the age of onset seems to be more nearly like that of the report by Blauner,[3] and not as late in life as that reported by Classen[7] or Waggoner et al.[18] The duration of the disease for those who have died has ranged from seven to thirteen years. One exception is to be noted. Member seven of generation III had the disease only three years, but died during the influenza epidemic of 1918.

Anticipation.—The phenomenon of anticipation does not seem to be involved in this genealogy. Due to the scarcity of records concerning the age of onset and the fact that the younger generation is watching for the symptoms and thereby recognizing the disease at an earlier age, the age of onset cannot be used as a means to study the possibility of anticipation.

On the other hand, the age at death of those affected can be used in the interpretation. In generation II, the average age at death of affected members was thirty-seven, with the ages ranging from twenty-eight to forty years. In generation III, the average age was thirty-eight, with the range from thirty-three to forty-eight. years. Records for generation IV give an average age at death of only thirty-two, and a range from twenty-nine to thirty-six years. Although the average in this generation is lower than that of the other two generations, it probably does not offer evidence in support of anticipation. The five living members in generation IV who are certain cases of ataxia have a range of ages from thirty to forty, with an average of thirty-four years. Their average age at death will obviously increase that for the generation; and at present, the range for all certain cases in the generation is equivalent to that for the second generation.

In histories of ataxia, members are usually known to be affected several years before their deaths; consequently, such a history may help to explain the so-called anticipation reported for some hereditary traits which develop late in life. Generation IV in this family gives a misrepresentation in that the average age at time of death, thirty-two years, represents the most severe cases. The milder cases, or else those members whose conditions of life cause the disease to act over a longer period of time, are still alive. Their present average age, thirty-four years, is two years higher than that of the affected members who died. In the final records for the known cases of ataxia of the generation, the increase in the average age will tend to remove any evidence of anticipation. If the disease were of a type which did not have a long duration before death, that explanation for anticipation would not be observable, even though it would still be active.

A Possible Sex Difference.—No condition of life is known which might make the disease more destructive in some members than in others. The ten certain cases in generation IV, however, do offer an interesting possibility. Five of the affected members are alive and five are dead. There are an equal number of affected males and females. Four of the five ataxic members who have died are females, four of the five living ataxic members are males. The average age for the four deceased females is thirty-three; that for the four living males, thirty-five years. Although this circumstance may be merely a matter of chance, records of the family do not so indicate. The results in generation IV are in accordance with the differences observed in generation III, in which the three affected females had an average age at death of thirty-six, the four males, thirty-nine years. It is also of interest that the four affected members of generation II were all females and that their average age at death, thirty-seven, is less than that of generation III, thirty-eight years, which included some males. If all the affected individuals who have died are considered for all generations, the eleven females show an average age of thirty-five, the six males, thirty-nine years. Although the disease is likely to develop in either sex, the female who inherits the defective condition, insofar as we can tell from these records, is likely to die earlier than the affected male. The data on the ages at onset are too scanty for accurate interpretation on variations of the onset.

Eugenic Consideration.—Until some therapeutic means is found to combat the disease, any control of its spread rests with the members of the family. This is not a disease which selects against itself by the elimination of ataxic individuals early in life, before children are produced. The presence of the defect does not seem to decrease the average size of the families. Several ataxic members even in the more recent generations have produced offspring after the onset of the disease.

An individual who had an ataxic parent can help to eliminate the disease from the family if he will regulate the production of his children. He should have no children until he has passed the age of onset for the disease. It is not possible to give an exact age at which a person can consider himself safe from the probability of developing the disease; but with the trait behaving so clearly as a dominant, it is possible to determine an age which can be said to be relatively safe. The age of the youngest known member with ataxia is twenty-seven years. Therefore a person should have no children before his age is twenty-seven years if his parent was ataxic, or if the parent died too early to show the disease. The person probably should wait until he is thirty or even thirty-three years old, the latest known age of onset in the family. If he then does not show the symptoms, he might consider himself as likely to be free from the hereditary defect, but still not necessarily so. If he does show symptoms of the disease and yet produces children, or if he takes a chance and produces children and then develops the disease, he must expect to pass

the disease on the average to one-half of his children. Those individuals whose parents passed the age of thirty-five years without developing the disease, especially if the grand-parents were also clear, probably will not pass the disease to their descendants.

Comment

The clinical diagnosis of olivopontocerebellar atrophy was confirmed by the gross and microscopic examination of the central nervous system. Grossly, the medullary olives and cerebellum were atrophic. Microscopically, there was extensive disappearance of the olives, the olivocerebellar fibers were almost entirely absent, there was demyelinization and vacuolization of the inferior and middle cerebellar peduncles, and lamellar degeneration of the cerebellar white substance was evident. Also, there was practically a total loss of Purkinje cells and the bodies and processes of those cells remaining were in various stages of dissolution, the cells of the dentate nuclei were similarly affected, and there was demyelinization and vacuolization of the superior cerebellar peduncles.

The degenerative changes in the olives, olivocerebellar fibers, inferior and middle cerebellar peduncles, and cerebellar white substance which were present in this case are the picture of olivopontocerebellar atrophy. If the atrophy is of long standing the histological changes may be more extensive. Transsynaptic degeneration may occur and the Purkinje cells, dentate nuclei cells, and superior cerebellar peduncles consequently may in turn be affected. Thus there was histological evidence of olivopontocerebellar atrophy plus secondary rather extensive transsynaptic degeneration in the instant case.

By transsynaptic degeneration, then, olivopontocerebellar atrophy may conceivably assume some of the characteristics of parenchymatous cortical cerebellar atrophy as did the case here reported. However, the latter condition cannot bring about retrograde degeneration of the olives, pons and cerebellipetal fibers. Degeneration of these structures is distinctive only of olivopontocerebellar atrophy. Finally, since there was no involvement of the spinal cord the case did not have the characteristic element of Friedreich's ataxia. Therefore, in addition to its positive histological picture of olivopontocerebellar atrophy, by exclusion it could not represent either parenchymatous cortical cerebellar atrophy or Friedreich's ataxia.

There was no definite destruction of the pontile nuclei in this case. Involvement of these nuclei would be indicated nevertheless by the presence of demyelinization and vacuolization of the middle cerebellar peduncles through which courses the pontocerebellar fibers, the afferent climbing fibers to the Purkinje cells. Also, the arcuate nuclei and the external and internal arcuate fibers seemed intact. Hassin and Harris[11] reported a case of olivopontocerebellar atrophy with involvement of all the cell bands of Essick, that is, the olives, pontile nuclei, and arcuate nuclei. Since these ganglion cell groups have a common origin from the lip of the rhomboid fossa it is tenable that all of the groups might be affected. However, in a primary degenerative process it is quite possible that one of the groups would be spared. The absence of demonstrable destruction of the arcuate elements in the instant case is therefore not material, particularly since otherwise there was complete histological accord with olivopontocerebellar atrophy, both actually and theoretically.

Several other members of this family in generation IV (Fig. 1), cousins of the one reported, have been studied clinically by us. Some had definite neurological findings indicative of olivopontocerebellar atrophy; others were entirely negative neurologically. None had the clinical signs of parenchymatous cortical cerebellar atrophy or Friedreich's ataxia. The members of this family were Christian people with no taint of alcoholism or specific infection and no nervous or mental disorder except the hereditary ataxia. The staring expression and unsteady gait were said to be the first signs of the disorder. In the women the ataxia seemed to appear soon after childbirth or to become more pronounced in those already affected. The terminal stage of the affection was said to be characterized by throat and lung trouble, not by any decrease in mental faculties. Death certificates of eleven deceased members of the family state the cause of death as follows: pneumonia (2), bronchopneumonia (1), lobar pneumonia (2), pulmonary tuberculosis (1), myocarditis (1), tricuspid regurgitation (1), paralysis (1), locomotor ataxia (1), and Marie's hereditary cerebellar ataxia (1).

Summary

1. The majority of the spinal and cerebellar heredofamilial degenerative disorders are not

entities but variants of a primary degenerative process in the central nervous system. There are three fairly distinct clinical and pathological entities, namely Friedreich's ataxia (hereditary spinal ataxia), Marie's hereditary cerebellar ataxia (olivopontocerebellar atrophy), and parenchymatous cortical cerebellar atrophy. By transsynaptic degeneration the second named may overlap the last named type of cerebellar atrophy.

2. A clinical and pathological report of a case of Marie's hereditary cerebellar ataxia (olivopontocerebellar atrophy) and a genetic study of that individual's family through six generations is presented.

3. Heredofamilial degenerative disorders have no known etiological factor other than a genetic error and consequently the current conception is that they can be overcome only through eugenic methods.

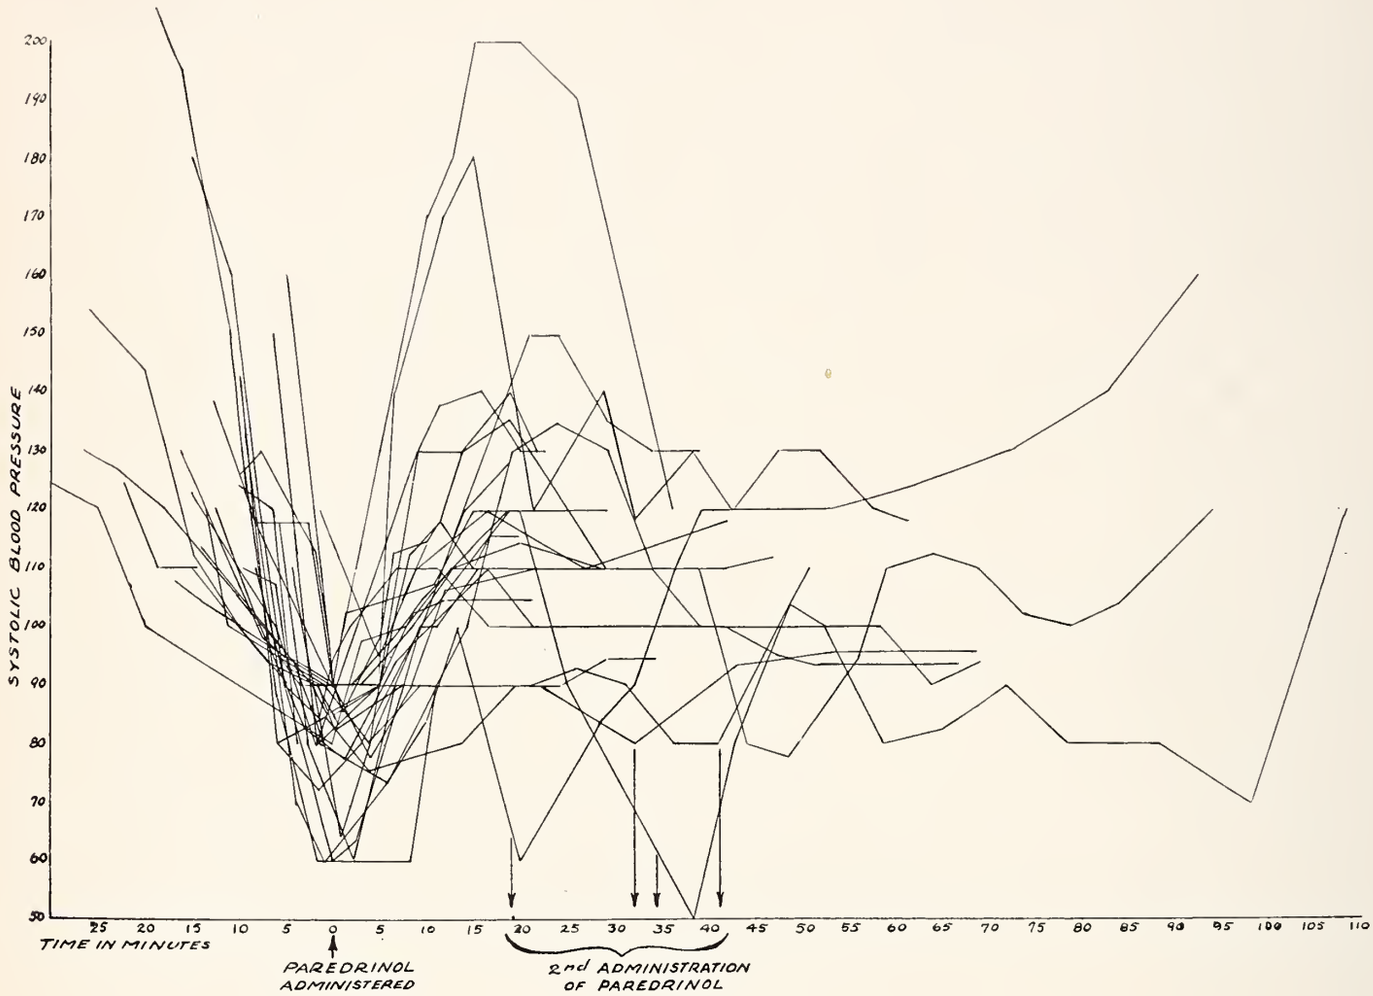
THE USE OF PAREDRINOL TO CORRECT THE FALL IN BLOOD PRESSURE DURING SPINAL ANESTHESIA*

DAVID P. ANDERSON, JR., M.D.

Austin, Minnesota

PAREDRINE and its N-methyl derivative, paredrinol (veritol; racemic parahydroxy-α, N-dimethylphenethylamine), recently introduced synthetic drugs of the epinephrine-ephedrine series, have been used to prevent and correct the fall in blood pressure during spinal anesthesia.[1] The effective pressor action of these drugs and their apparent advantage over other similar drugs prompted us to investigate further the use of paredrinol during spinal anesthesia. Paredrinol, rather than paredrine, was selected because of the wider pharmacologic and clinical background already established for this substance.[2,3] The two drugs, however, produce similar physiologic effects, with but a slight difference in intensity.



Paredrinol is effective when given by mouth, intramuscularly or intravenously. We have, thus far, employed only the oral and the intramuscular routes of administration, and in this report we shall discuss only those cases in which paredrinol was administered intramuscularly during spinal anesthesia because of a rapid, marked fall in blood pressure. We have used paredrinol to prevent the fall in blood pressure during spinal anesthesia, but a more extensive comparison with other pressor drugs is necessary for definite conclusions.

We have administered paredrinol over a period of four months to thirty-one patients who had a rapid lowering of the blood pressure during spinal anesthesia. This group of patients was given no pre-anesthetic pressor drugs and no atropine. Intravenous fluids were not administered during the course of the anesthetic, except in the two cases where the paredrinol failed to maintain an adequate systolic blood pressure. Paredrinol was given intramuscularly when

*Paredrinol for this investigation was supplied by the Research Department of the Smith, Kline and French Laboratories, Philadelphia.

the systolic blood pressure fell below 90 mm. mercury, and the administration was repeated if a secondary fall in pressure occurred or if there was an inadequate response to the first injection. to maintain an adequate systolic blood pressure.

Paredrinol, even when repeated, was ineffectual in correcting the blood pressure fall in two of the thirty-one cases. One patient was a woman, aged sixty-five, who had a carcinoma of the common hepatic duct. A prolonged exploration was required to establish the diagnosis, the amount of the anesthetic drug was much larger than usual, and the patient's general condition was not satisfactory prior to the operation. The other patient was a man, also aged sixty-five years, with a perforation of the gall bladder. In each of these cases the blood pressure was restored to a satisfactory level by the administration of intravenous fluids. The experience in these cases forced us to return to our former practice of administering intravenous fluids or whole blood transfusions during the course of the operation in critically ill patients requiring extensive surgical procedures under spinal anesthesia. The fact that paredrinol alone will not maintain an adequate blood pressure in such cases is not surprising in view of the experimental observations of Stead, Kunkel and Weiss

The usual intramuscular dose of paredrinol was 20 mgm. An initial injection of 40 mgm. of paredrinol was given in an early case, a woman of forty-eight years who had a pre-anesthetic systolic blood pressure of 154 mm. mercury, and a rapid rise of the systolic blood pressure from 90 to 200 mm. mercury was noted. The 20 mgm. initial dose was adopted as a routine because of the untoward effects of the larger dose in this case, and in elderly or arteriosclerotic patients an initial dose of only 10 mgm. was frequently used.

The initial dose of paredrinol was sufficient to correct the fall in blood pressure and to maintain a satisfactory systolic blood pressure above 100 mm. mercury in twenty-three of the thirty-one cases. A single administration of the drug was sufficient to maintain a normally low systolic blood pressure in two additional cases. In four of the thirty-one cases, a second administration of paredrinol (10 to 20 mgm.) was required

on the mode of action of paredrinol.[3] The drug is not of value in all types of syncope and it is particularly unlikely to be of benefit in cases of shock from fluid loss.

There were no operative or hospital deaths in this series of cases, nor were there any postoperative complications which could be attributed to the anesthetic. No untoward symptoms resulted from the administration of paredrinol, except the transient hypertension noted in an early case. There was a striking absence of marked stimulating effects on the cortical centers, which frequently occur with other pressor drugs. Cardiac arrhythmias and marked tachycardia did not occur.

Conclusions

Paredrinol, a synthetic pressor drug of the epinephrine-ephedrine series, is effective in correcting the blood pressure fall during spinal anesthesia. This drug possesses certain advantages over other pressor drugs in that it does not cause excessive cortical stimulation, tachycardia, or cardiac arrhythmia. We feel that further clinical investigation of paredrinol is indicated.

CASE REPORTS

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL
Frank C. Andrus, Pathologist

A white woman, forty-one years of age at the time of death, was first seen at the hospital in August, 1934, when she was thirty-five years of age. She complained of attacks of nervousness, headache, palpitation of the heart, vomiting, and tremor of the hands. With these attacks of palpitation, she became extremely weak and pale. She did not faint. The attacks came on with equal frequency during the day or night. Physical examination was negative except for varicose veins. The blood pressure was 120/90 and the pulse rate was 110 per minute. A diagnosis of "cardiac neurosis" was made.

She was next seen in June, 1935. At this time her eyes were refracted and the optic fundi were found to be normal. In November, 1936, the patient stated that she had continued to have the episodes described above. The pulse rate was 132 per minute and the blood pressure was 140/90. In March, 1938, the blood pressure was 145/90. Laboratory examination revealed normal urine and blood counts. The Wassermann was negative. She had had no dyspnea, orthopnea, edema, or chronic cough. Other history was negative. She had had two pregnancies. Her father had died of a stroke. Three sisters were living and well. Her husband was suffering from dementia paralytica.

In November, 1938, the pulse rate was found to be 120 per minute and the blood pressure 150/90. The patient was admitted to the hospital at this time and while there had several attacks of tachycardia during which she would become extremely weak and perspire profusely. The skin would blanch and she would become very apprehensive.

She was not seen again until June, 1939, when she returned to the Eye Clinic. She continued to complain of severe headaches and ophthalmoscopic examination revealed papilledema of the right eye with hemorrhages and star-shaped exudates in the right macular region. While in the clinic, the patient had an attack of palpitation of the heart. The pulse was 160 per minute. A systolic murmur was heard over the precordium. The blood pressure varied between 170/90 and 155/100. The patient became faint and the pulse became irregular. It later became regular at a rate of 80 per minute. No murmurs were audible at the slower pulse rate. At another time the blood pressure was found to be 202/138. A six-foot heart plate showed no enlargement of the cardiac shadow. The patient continued to be very nervous and had occasional attacks of weakness, nausea, headache, and tachycardia. The pulse rate was 128 per minute.

In August, 1939, an ophthalmoscopic examination revealed hypertensive retinitis. There was marked compression of the veins where they were crossed by the arteries and many star-shaped exudates were seen. There was papilledema and numerous areas of local attenuation of the lumen of the retinal arteries. In June, 1939, the blood pressure was 200/110.

She was admitted to the hospital for the last time in April, 1940, in a critical condition. She had experienced nausea and vomiting in the morning and gradually lapsed into a coma. The blood pressure was 260/140. There was auricular fibrillation. The right leg and the right arm were flaccid and tendon reflexes were absent. The Babinski reaction was positive on both sides. Shortly after admission, the heart became regular and the blood pressure dropped to 190/110. A lumbar puncture revealed a pressure of 300 millimeters of water. Examination of the eyegrounds now revealed choked discs of four to six diopters and hypertensive retinitis. A venesection was performed

and 500 c.c. of blood was withdrawn but the blood pressure did not fall remarkably. She expired on the same day.

The clinical diagnoses were: (1) Essential hypertension, and (2) cerebral hemorrhage.

At autopsy the following significant findings were noted: The heart weighed 260 grams. It was not enlarged. The valves were all normal. The coronary arteries were not sclerotic. The lungs were negative. The liver, spleen, and the intestinal tract were normal. The left adrenal gland was negative. The right adrenal gland was greatly enlarged. It measures 11x6x6 cm. A narrow shell of cortex was distributed over its surface. The inner portions of the tumor were composed of brown, partly liquified tumor tissue. The tumor weighed 220 grams. The kidneys were normal. Rather marked atherosclerosis of the aorta and of the cerebral arteries was present. There was a massive hemorrhage in the left cerebral hemisphere which communicated with the left lateral ventricle which was filled by a blood clot.

Anatomical Diagnoses: Pheochromocytoma of the right adrenal, cerebral arteriosclerosis with cerebral hemorrhage.

Discussion

Dr. Harold Freedman: The cortex and the medulla of the adrenal gland have entirely unrelated functions. The medula is derived from the neural crest of the ectoderm and is the portion of the gland which produces adrenalin. Three tumors of the adrenal medulla are well recognized. They are: The benign ganglioneuroma, the malignant neuro-epithelioma, which most commonly occurs in children and young adults, and the pheochromocytoma. This last tumor derives its name because the cells are stained by chromium salts. The epinephrine content of this tumor was determined and was found to be about 800 milligrams. These neoplasms were not clearly recognized until about 1922. Since then a number of cases have been reported, some patients being cured by surgical removal of the tumor. The symptoms this patient had are quite typical, namely, episodes of headache, palpitation of the heart, tachycardia, apprehension, and exhaustion. In some of the reported cases, movement of the trunk to the side of the tumor may bring on an attack. Other patients have found that anything which causes excitement precipitated an episode. If the diagnosis is suspected, the tumor may be localized by finding displacement of the kidney on the affected side or by outlining the mass by injection of air into the perirenal space. Patients suffering from these tumors are notoriously poor surgical risks. Two patients died in the hospital during an attack the day before they were to be operated upon for removal of the tumor. The common causes of death are cerebral hemorrhage, acute or chronic heart failure, or sudden death due to hyperepinephrinism. The tumor is usually one found in adults. Its incidence is equal in the sexes and either adrenal gland may be involved. The advanced atherosclerosis that this patient had is probably related to the elevation in blood pressure rather than to the excessive secretion of epinephrine. In rabbits, at least, long continued administration of epinephrine produces changes limited to the aorta, but does not produce atherosclerosis such as was seen in this patient.

Dr. E. T. Bell: Here is a woman who had a benign tumor who could have been cured of her high blood pressure by removal of that tumor. This is a most interesting case. I doubt if there is one like it in the literature with this long story and producing, towards the end, a persistent elevation in blood pressure.

Dr. George E. Fahr: These tumors may occasionally produce constant hypertension. In retrospect, two things in the patient's history indicate the correct diagnosis. In the first place, the patient had an almost constant sinus tachycardia. In the second place, the attacks of palpitation were accompanied by extreme exhaustion.

Dr. E. T. Bell: This is the most remarkable sort of tumor, a tumor that functions. Nearly always a functioning tumor is benign. Other examples of tumors which carry on a function are parathyroid adenomas, granulosa-cell tumors of the ovary, and adenomas of the thyroid and hypophysis. This tumor continues to secrete adrenalin in just about the amount that the patient can handle at first, except during the episodes of hypertension and palpitation of the heart with tachycardia. This tumor has nothing to do with the cortex of the adrenal. Cortical tumors sometimes cause a little hypertension, but never anything like this. They also produce sex changes in women and young males. The elevation in blood pressure accentuated the process of atherosclerosis and thus predisposed the patient to the fatal cerebral hemorrhage.

BONE FORMATION IN OLD SCAR

A. L. PERTL, M.D.
Canby, Minnesota

THE patient, P. J. R., male, aged forty-one, was operated upon for a perforated gastric ulcer Aug. 11, 1938. He had an uneventful recovery and the wound healed by primary intention.

On Aug. 26, 1939, he had a cholecystectomy done, for a chronic infected gall bladder and many stones. The wound healed by primary intention.

On April 27, 1940, he was again admitted to the hospital for lobar pneumonia, was treated with only sulfapyridine and was discharged May 9th.

On October 1940, he felt a hardness in the upper one-third of the wound made in August 1938. On November 11, while shoveling snow, he felt a sharp pain and he could feel a foreign body under the skin about 1.5 inches long. Thereafter all bending and shoveling would produce sharp pains.

On March 22, 1941, the foreign body was removed under local anesthesia. It proved to be a piece of bone 4.2 cm. long, 5 mm. wide, 2 mm. thick on one edge and tapered down to a sharp edge. The upper point was very sharp. The skin and subcutaneous tissue was very, very hard in the upper half of the old scar or for a distance of about 3 inches. The bone was imbedded in the muscle fascia.

A report from Dr. E. T. Bell, of the Pathology Department of the University of Minnesota, stated that the foreign body was bone, and he recalled only one other similar instance. The wound is healing slowly, the firmness in the skin is gradualy disappearing, and the patient is free from all pains.

HISTORY OF MEDICINE IN BROWN COUNTY

Compiled by George B. Weiser, M D.

(Continued from April issue.)

Later Physicians in New Ulm

Dr. Ora C. Strickler, a native of the town of Markham, Ontario, Canada, was born January 7, 1863. His parents, who were Pennsylvania Mennonites, moved to Ann Arbor and later to Lansing, Michigan. Dr. Strickler graduated from the High School at Markham, Ontario, entering the Medical Department of the University of Michigan and graduated therefrom June 25, 1885.

Immediately after his graduation he located at New Ulm, Minnesota, where he continued practising until his death. He took a postgraduate course in Berlin, Germany, in 1888 and 1889.

During his practice at New Ulm he became one of the best known physicians and surgeons in this part of the state. He was a member of the county and state medical societies in which he took a warm and active interest. He took great interest in the civic affairs of his community and served as a member of the Board of Education.

He was local surgeon of the Chicago & Northwestern Railway and of the Minneapolis & St. Louis Railroad up to the time of his death. In 1898 he was president of the State Board of Medical Examiners; from 1900 to 1906, a member of the Board of Regents of the University of Minnesota. He was a Republican in politics and gave much attention to local political affairs. He was a York Rite and Scottish Rite Mason; a member of Zuhrah Temple order of the Mystic Shrine, Minneapolis. In all of these branches he took an active interest.

Dr. Strickler died March 12, 1928.

Dr. Jacob C. Rothenburg graduated from the University of Michigan Medical Department in 1885. He located in New Ulm from January to November, 1887, when he removed to Springfield, Minnesota, where he continued in active practice until the time of his death in 1939.

During his career at Springfield Dr. Rothenburg took an active interest in promoting the prosperity of his community. He had a lucrative practice in Springfield and adjacent territory. He took an active interest in the Masonic bodies, was a Past Master of his local lodge; Past High Priest of Springfield Chapter, a Knight Templar and Scottish Rite Mason. He served as coroner of Brown County and was one of the organizers of the State Bank of Springfield, of which he was vice president and director.

He was given a reception by the citizens of Springfield commemorating his fifty years of practice in that community.

Dr. Louis Albert Fritsche was born May 28, 1862, on his father's farm in Lafayette township, Nicollet County, Minnesota, within two miles of New Ulm. He received his education at Saint Peter High School and taught district school

for one year. He entered the Medical Department of the University of Michigan September 24, 1884, graduating therefrom in medicine June 30, 1887. On July 1, 1887, the new medical law went into effect requiring those applying for license to practice to pass the State Board of Medical Examiners. There were three candidates to pass the Board and Dr. Fritsche was awarded and registered as Number 1.

On August 14, 1887, he opened an office in New Ulm and practised there until the latter part of April, 1889. He then went to Germany to take up postgraduate work and specialized in surgery in Berlin. During his third semester, from April to August, he was second assistant to that famous surgeon, Prof. Julius Woelf.

He was a member of the 10th International Congress which convened in Berlin August 6 to 13, 1890. Dr. Fritsche returned home October 15, 1890, and reopened his office at New Ulm, continuing the practice of medicine until his death in 1931. He was a past president of the Southern Minnesota Medical Association, and was health officer of New Ulm from 1890 to 1894. He served as a member of the Pension Examining Board, and as coroner of Brown County for four terms, from 1896 to 1904. In 1900 he was appointed a member of the State Board of Medical Examiners for three years and last year was president of the Board.

Dr. Fritsche was elected mayor in 1912 and was twice reëlected. In the year 1900 he was elected president of the Brown County Bank, was vice president of the New Ulm Roller Mill Company and directors in several industrial enterprises. In July, 1914, he joined a Commission of Mayors to attend the International Congress of Municipal Executives held in London. In politics he was a Democrat and as delegate attended many state conventions. Later in life he assisted in organizing the Farmer Labor Party and became an aggressive leader until his death in 1931.

Dr. Fritsche, who established the Fritsche Clinic, had four sons graduated in medicine who became members of the clinic. This is a record that has no counterpart in the State of Minnesota.

Dr. Jacob L. Schoch, a native of Selingrove, Pennsylvania, was born in the year 1862. After receiving his education at the Gettysburg College, Pennsylvania, he taught in a rural school for one year, then entered the Medical Department of the University of Michigan, graduating in the year 1885.

He practiced medicine at Walton, Kansas, one year, then established an office in Chicago. He came to New Ulm in 1888 where he continued his practice until his death, which occurred September 22, 1934. He succeeded Dr. A. W. Mueller and also took charge of Dr. Strickler's practice during his absence in Europe. He was a member of the Brown County and Minnesota Valley Medical Societies and the Minnesota State Medical Association.

Dr. Schoch served as a member of the Pension Examining Board, meeting at Mankato, and later was appointed by Governor Merriam as a member of the State Board of Medical Examiners. Throughout his medical career he had a lucrative practice.

Dr. Schoch engaged in many civic enterprises, was one of the organizers and a large stockholder in the present Brown County Agricultural Society. He promoted the first telephone system in the city of New Ulm. He established the New Ulm Investment Company, of which he was the largest stockholder, and was the president of the company until his death. Many residences have been erected by this company. He was a large stockholder and president of the New

Ulm Roller Mill Company and formerly organized and had interests in the Western Lumber Company in Idaho.

Dr. Schoch was not only a successful practitioner of medicine but was recognized as one of New Ulm's prominent business men.

Dr. C. J. B. Hirsch graduated from Rush Medical College in 1868 and located at Black River Falls, Wisconsin. He came to New Ulm in 1891 and moved to Audubon in 1899, where he died October 16, 1901. While located at New Ulm Dr. Hirsch had a large practice, particularly among the Scandinavians.

Dr. George B. Weiser was born September 7, 1857, in Dalmatia, Northumberland County, Pennsylvania, the son of Dr. Charles S. Weiser. He received his early education in the public schools, Freeburg Academy, Benysburg Seminary and Sunbury Academy. He read medicine with his preceptor, Dr. B. L. Kerchner, Dalmatia, Pennsylvania, and entered the Jefferson Medical College, from which he graduated in March, 1879.

On March 28, 1879, Dr. Weiser opened an office at McKees Half Falls, Snyder County, Pennsylvania. In March, 1893, he came to New Ulm, Minnesota, having passed the State Medical Board examination in the fall of 1892 and has been in continuous practice at New Ulm to the present time (1940). He has been engaged in the practice of his profession over sixty-one years.

When the Minnesota Legislature passed a law to establish a State Sanatorium for tuberculosis, an advisory commission was appointed by Governor Van Zandt to select a site for the sanatorium and erect buildings to the extent of money appropriated by the Legislature. The Advisory Commission consisted of Dr. H. L. Taylor, Saint Paul, Dr. J. L. Camp, Brainerd, Dr. G. C. Watham, Warren, and Dr. George B. Weiser, New Ulm.

In the year 1917 Dr. Weiser was appointed a member of the State Board of Medical Examiners, serving for sixteen years, until 1933. He was at one time president of the Board. He is a past president of the Brown County Medical Society and the Redwood-Brown Medical Society; member of Southern Minnesota Medical Association, Minnesota State Medical Association, and fellow of the American Medical Association.

Dr. Weiser was a member of the Electoral College during the Harding campaign, also for the Taft campaign. In the Masonic York Rite bodies he is a Past Master, Charity Lodge; in the Scottish Rite bodies, a 32nd Degree Mason, Winona Consistory. He is a life member of Zuhrah Temple Mystic Shrine, Minneapolis; honorary member Masonic Veteran Association. He was a member of the Board of Education for twenty-two years, for twenty of which he served as president. He is a former vice president of the Brown County State Bank and a charter member and director of the State Bond and Mortgage Company.

Dr. William P. Pfisterer, a native of New Ulm, graduated from the University of Pennsylvania Medical School in 1890. He practiced in New Ulm from July, 1890, to July, 1891, when he moved to Winthrop, Minnesota, where he continued to practice until his death in the later nineties. He was a member of the Minnesota Valley Medical Society.

Dr. Gustav Fischer, born in New Ulm, was principal of the New Ulm High School previous to taking up medicine. He graduated from the Jefferson Medical College, Philadelphia, in 1896, and located at New Ulm the same year. He remained there until October, 1898, when he moved to Minneapolis, continuing his

practice there until his death in 1931. Dr. M. M. Fischer, city physician of Duluth, is his son.

Dr. George F. Reineke was born in Blooming Grove township, Waseca County, May 13, 1871, attended school at Saint Paul College, and graduated from the University of Minnesota Homeopathic Medical School in 1896. Immediately thereafter he located at New Ulm for the practice of his profession. In 1903 he went to Europe (Vienna) to take a postgraduate course in eye, ear, nose and throat work. Returning to New Ulm, he established himself in that specialty, and has continued practicing to the present time (1940).

Dr. Reineke has been a member of the Academy of Ophthalmology and Otolaryngology since 1926. He has been coroner for Brown County since 1910, was at one time health officer of New Ulm and a member of the school board from 1904 to 1919. His son, Harold G. Reineke, is a prominent roentgenologist in Cincinnati, Ohio.

Dr. Reineke was a delegate to the General Conference when the three Methodist churches united—Methodist Episcopal, Methodist Episcopal South and Methodist Protestant Church.

Dr. A. Franklin Strickler graduated from the University of Michigan Medical Department in 1898 and took a postgraduate course in Germany. On his return from Europe he associated himself with his brother, Dr. O. C. Strickler, in New Ulm. After several years in New Ulm he moved to Sleepy Eye, where he continued to practice until his death.

Dr. Mary Strickler, wife of Dr. A. Franklin Strickler, was associated with him in the practice of medicine at Sleepy Eye.

Dr. George F. Beachler graduated from the Medical School at Wooster, Ohio, in the year 1895. He located at New Ulm several years later for a brief period of time. No record can be found concerning him after he left New Ulm. He specialized in the treatment of hernia by using local injections.

Dr. Edmund W. Bayley graduated from the Medical Department of the University of Kansas City in 1898. He located in Minneapolis and moved to New Ulm in 1901; after three years' practice in New Ulm he moved to Sleepy Eye. In 1907 he became a Contract Surgeon in the regular army. He is now retired and resides in California.

Dr. Otto G. Wicherski, native of New Ulm, graduated from Rush Medical College in 1904 and located in New Ulm in 1905. In 1906 he moved to Frankfort, South Dakota. In 1907 he moved to San Diego, California, and was appointed city physician, serving until the time of his death.

Dr. Joseph H. Vogel, well-known and popular physician of New Ulm, was born in New Ulm, March 28, 1879. He graduated from Rush Medical College in January, 1903, and immediately commenced the practice of medicine in New Ulm, where he has successfully been engaged ever since. At one time he served as health officer for New Ulm, and has been a member of the city council, as well as the school board.

He is president of the Farmers and Merchants State Bank of New Ulm, director of the State Bond and Mortgage Company of New Ulm, and is also engaged in a number of financial enterprises.

Dr. Frank W. Pfisterer, a native of Brown County, graduated from Marquette University Medical School, Wisconsin, in the year 1913. He located at New Ulm in 1915, but the latter part of that year moved to Milwaukee, thence to Markeson, Wisconsin. At the present time he is practicing medicine in Milwaukee.

Dr. Gottfried Schmidt located at New Ulm and later moved to Sleepy Eye. His biography appears under the heading, "Sleepy Eye Physicians."

Dr. Otto John Seifert, well-known physician and surgeon, was born in Sigel township, Brown County, February 5, 1888. He spent several years at Saint Thomas Military Academy, then entered the University of Minnesota, from which he graduated in 1910 with the degree of Bachelor of Sciences. He then entered the Medical Department of the University of Minnesota, graduating in the year 1912. He served as intern at the City Hospital, Minneapolis.

In 1912 he located at New Ulm where he has continued the practice of medicine and surgery to the present date (1940). During the World War he served overseas with the rank of Major in the Medical Corps, U. S. Army, in command of Hospital Unit No. 58.

After the war he resumed his practice at New Ulm, where he was health officer for seventeen years. He is a member of the Redwood-Brown County Medical Society, the Minnesota State Medical Association, and the American Medical Association.

He is a member of the Minnesota Radiological Society and American Radiological Society. He took postgraduate courses in Berlin, Vienna, and New York. He is a member of various civic and fraternal organizations and is State Master of the Knights of Columbus.

Dr. Carl W. Scherer, native of New Ulm, graduated from the University of Michigan Medical College in 1907 and was licensed to practice in Minnesota in June, 1907. He was located at New Ulm from 1907 to 1908, practiced in Ruthton, Minnesota, February, 1908, to January, 1909, and entered the Army Medical School, Washington, D. C., in 1909. He served the Madera-Mumore Railroad, Brazil and Bolivia, South America, from 1910 to 1912, inclusive. He then took a postgraduate course in Munich, in 1912 and 1913. Upon his return to the United States he became instructor in Pediatrics at the University of Minnesota, 1914-1915, then moved to Fargo, North Dakota, where he specialized in pediatrics, 1916-1917. From 1917 to 1933 he practiced pediatrics in Duluth and has been health officer, from 1933 to the present time (1940), for St. Louis County, Minnesota.

(To be continued in June issue.)

President's Letter

OUR CENTURY OF PROGRESS

ONE hundred years ago this year, the first civilian, learned in medicine, came to settle in this territory. What visions of the future could he have had as he and his associates made their way into the virgin wilderness finding broad rivers and lakes unknown to the paddles of white men, forests of unbounded beauty and unlimited prairies stretching to the Red River Valley of the North! All these were known only to the aboriginal Indians for ages before the coming of the first white man.

What a surprise he would have if he could return today to find two and one-half million people, descendants of all the nations of the world, among these same surroundings with every luxury of modern civilization at their beck and call. Railroads and broad highways carrying traffic to every city and hamlet, progressive cities and villages dotting the landscape. Well-cared-for farms producing the grains for the mills, and herds of stock, the essentials for the packing plants. The iron mines of the North sending their wealth to the Twin Ports to be carried on the shipping lanes to the east, and the forests and quarries producing the materials for untold numbers of necessary industries.

Surely a century of progress has passed since the coming of Dr. Christopher Carli in 1841.

And then we turn the pages of state history to 1853 and find a small group of medical men gathered in the first meeting of our association to discuss the future of medicine; earnest and interested in their work the same as we are today. Did they vision the progress that eighty-eight years would bring? They certainly knew that if progress was made it meant close association and a tolerant attitude one toward the other, that a strong spirit of coöperation was necessary to the success of the embryo association. They must have felt this or they would not have met together.

What a surprise would await them could they see the progress of medical science as set forth in our annual meeting this month, when again several thousand medical men will meet for essentially the same purpose that they did.

Truly, the members of the Minnesota State Medical Association have much to be thankful for: a fine organization with a true sense of civic responsibility, progressive to the very nth degree. We are essentially interested in our obligation to the people of the State economically and professionally.

Let us, as we again gather together, dedicate ourselves to close coöperation one to another and to a further sense of obligation for the conduct of our association.

Let us work together for the good of the people, of our state and nation; the founders of our association left us a heritage which we must continue to hold sacred.

B. J. Branton, *President*
Minnesota State Medical Association

THE CRIMINAL A.M.A.

SO the A.M.A. and the Medical Society of the District of Columbia are convicted of being criminally guilty of violation of the Sherman Act! The officers of these organizations were quite inconsistently acquited, as well as the other individual doctors indicted. We understand the case is to be appealed to a higher court.

To anyone who had the patience to plow through the reams of testimony which appeared in the *A.M.A. Journal,* much of the evidence might well have been considered irrelevant, incompetent and immaterial. The charge to the jury given by Associate Justice Proctor offered, however, much food for thought. There were some fine distinctions involved and much could be said, and was said, on both sides.

The purpose of the indictment was, without doubt, to undermine the resistance of organized medicine to new and unapproved forms of group practice. Hundreds of new methods are already being tried out by physicians throughout the country to make medical service more available to the public at large. Certainly, the majority of the medical profession, and this means the organized profession, is in a better position to judge the comparative values of new methods of medical practice than any other element in society. The members of the organized profession, it seems, can legally express their disapproval of an organization like the Group Health Association, but cannot legally take any steps that might interfere with the association's activities.

It is perhaps consoling that we, as individual members of the A.M.A., are not adjudged criminals and that the hospitals that barred their doors to non-members of the A.M.A. were not criminals.

Now that doctors, from the standpoint of the Sherman Act, are engaged in trade, perhaps we should follow the suggestion made in one newspaper editorial and behave like a union, have a pay schedule, demand full pay for what we now render to charity (for what union contributes in any comparable way to public charity), a thirty-five hour week and time and a half for over time.

After all, we are members of a profession and not a trade; the distinguishing feature of a profession being that financial compensation is not the main consideration.

It does not seem right that elements in our society should be resorting to expensive legal battles at a time when every effort should be expended to prepare for probable serious exigencies. The expense of this litigation has necessitated certain curtailment in A.M.A. activities. Nevertheless, it is incumbent on the organized profession to fight for its rights and to resist the tendency in governmental circles to overregulate medical practice.

LEGAL ASPECTS OF BLOOD GROUP HEREDITY

IN THIS issue we are publishing the report of the committee of the Minnesota County Attorneys' Association on the use of blood tests to exclude paternity. It is a subject that the rank and file of the medical profession know little or nothing about. We are, therefore, pleased to have the opportunity to present this report.

The authors admirably present the scientific facts regarding blood groups and then even more admirably present their recommendations that Minnesota wait awhile before following the lead of New York, Wisconsin and other states in passing a law relating to the use of blood grouping in proving non-paternity.

While the hereditary transmission of blood characteristics follow well established laws, there are factors which limit the use of blood tests in legal cases involving paternity. At best the test is of value only in a negative way. It has a chance of proving, in sixteen cases out of one hundred, that the wrongly accused is not the father. It is true that if one were wrongly accused, such a chance of proving oneself innocent would doubtless be worth taking. On the other hand there are certain limitations to the use of the test which account for the committee's recommendations that the passage of such a law be deferred. To be of any legal value the honesty and competence of the laboratory expert must be beyond question. Then there is the reluctance of doctors to become involved in litigation, the cost of such a specialized procedure, and the feeling on the part of the committee at least that the passage of such a law is not likely to stimulate the development in Minnesota of specialists competent to do these tests. Perhaps the most important reason for the committee's recommendation is the difference of opinion among medical authorities as to the age when the child manifests his blood group. This, too, often tends to the postponement of a trial for a year or two until certainty can be felt as to the permanency of the child's blood group.

We cannot but agree that the passage of legislation in Minnesota in line with that in our sister state would likely to be useless legislation, of which we already have a plenty. It seems strange to one not a lawyer that legislative enactment should be necessary before one could take advantage of proven facts in relation to hereditary transmissions should the occasion arise. Perhaps it were simpler to be like Cæsar's wife.

MAN OF VISION

BEFORE 1908, by which time he was forty-two years of age, Abraham Flexner had never set foot within a medical school. His whole life had been spent in the field of general education, as a student and a teacher. Early in that year his first book, *The American College,* was published. It was, to use his own words, a severe criticism of the elective system, the lecture system, and assistantships, as he had observed them at Harvard in the year 1905-1906. It was so full of revolutionary ideas that it fell flat, because no one was prepared to act on the sweeping crticism he had made. But it was read by Dr. Henry S. Pritchett, who had become president of the recently established Carnegie Foundation for the Advancement of Teaching and made enough of an impression on him that he asked Flexner to undertake the work of making a survey of medical schools, of which there were then 155 in the United States and Canada. Flexner accepted after some hesitation, for he felt that his lack of any medical education whatsoever would be a handicap, but Dr. Pritchett said that was exactly what he had in mind; that the schools should be studied from the standpoint of the educator rather than from the point of view of the practitioner.

Flexner spent a little over a year and a half in this work and in preparing "Bulletin Number Four," which contains his findings in full detail. It is a merciless exposure of the conditions he found and shook the very foundations of the entire structure of the medical education of a generation ago. The results were cataclysmic. Many schools closed their doors, others merged and all which survived were compelled to inaugurate a program of reorganization directed toward greatly improved standards. Flexner not merely pointed out the weaknesses but set up a framework of constructive suggestion which was widely followed in the succeeding years.

Interest in this epochal work is stimulated by reading the recently published life story* of its creator which gives the intimate details of

*I Remember. The Autobiography of Abraham Flexner, New York, Simon and Schuster, 1940.

the author's efforts in this as well as in other important connections. Well written and easily read, as one would expect from the hand of a scholar, it tells in modest fashion the history of a man whose whole aim in life was directed toward improving existing conditions by rational and practical methods. That he was able to be successful in these various undertakings seems to be due largely to the fact that he was a man of keen perception, fundamentally sound and fearless in his convictions. But whatever the reason, medicine owes him a tremendous debt for his courage and far-sightedness in bringing about the changes which led to its present high educational estate.

GILBERT COTTAM.

SAMPLES FOR BUNDLES FOR BRITAIN

THE reported move in certain quarters to give aid to "Bundles for Britain" by collecting physicians' samples of pharmaceuticals and sending them to England is well meaning. On further consideration it should be evident that packaging this heterogeneous material and shipping it abroad would largely be "love's labor lost." It is not suprising that the pharmaceutical houses have protested this move, for the samples are sent to physicians for a specific purpose. Also, most of the producers have been generous in making donations of vitamin capsules and other needed pharmaceutical products which are of assistance in a more practical way.

The wishes of the pharmaceutical houses are certainly entitled to consideration.

DOCTORS FOR BRITAIN

IT is not surprising that the demand for physicians in Great Britain has exceeded the supply. What with the needs of the army and the war casualties extended to the civilian population the medical profession finds itself overworked. The British Red Cross has, therefore, recently requested the American Red Cross for upwards of 1000 young members of our profession to serve either with the Royal Army Medical Corps or with the Emergency Medical Service, a civilian organization under the Ministry of Health. Applicants must be citizens of the United States, not over forty years of age for service in the Royal Army Medical Corps, nor over forty-five years of age for appointment to the Emergency Medical Service. Physical and professional qualifications will have to be met.

Doctors accepted for the British Army will be commissioned as lieutenants the first year with pay of $1456.50 and a bonus of $400 at the end of the year. The second year they will be promoted to captaincy with pay of $1800 and a bonus of some $600 at the end of the year. Contracts are to be made for one year. Doctors accepted will be provided with transportation and the same disability compensation as is provided the British officers. Volunteers are liable for service wherever British troops are located.

Further information concerning "Doctors for Britain" can be obtained from the Red Cross Headquarters in Washington, D. C.

One Hundred Years of Medical Practice in Minnesota

Attention is being called in the Program of the State Medical Meeting to be held this month, to the fact that just one hundred years ago this month, May 24, 1841 to be exact, the first civilian physician came to Minnesota to practice.

This physician was Dr. Christopher Carli, who was born in Franklin-on-the-Main and was educated at Heidelberg University. He was thirty years old when he arrived at what is now Stillwater and his territory ranged from Lake Pepin in the south to Lake Superior in the north, and from Menominee, Wisconsin, westward. His calls were made on foot, on skates or snowshoes, by canoe and horseback.

How the methods of communication and transportation have changed in the past 100 years! Even more has medical science progressed in this comparatively brief period of time.

Child Health in England

According to the Statistical Bulletin of the Metropolitan Life Insurance Company, the infant mortality in England for the first quarter last year was seventy-seven per annum per 1000 live births, compared with sixty-five per 1000 the same quarter in 1939. This was accounted for by the influenza epidemic which struck England in the early part of last year.

Although the trend in contagious diseases of childhood tended to rise in the latter part of 1940, the only serious increase was in cerebrospinal meningitis.

London today has only one-sixth of its previous child population. In spite of this, air raids brought death to 2,487 children in England in 1940. This number was 11 per cent of the total civilians killed.

Hitler should be proud and pleased.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

CALL FOR ACTION

To the Medical Profession of Minnesota:

As a result of the verdict given at the recent trial of the Federal Government against the American Medical Association the medical profession is "on the spot" as far as public opinion is concerned. This verdict states that the American Medical Association is guilty of a criminal conspiracy to restrain trade as charged by the Department of Justice. In all probability the officers of the American Medical Association will appeal the verdict and, if necessary, move for a retrial in the higher courts.

In the meantime public opinion may well be prejudiced against organized medicine by the results of the trial. Already steps are being taken by those who oppose our code of medical ethics and the principles of organized medicine to take advantage of the situation. Unless the public can be adequately informed as to underlying factors, organized medicine, and with it the present standards of medical practice, may be placed in a precarious position.

The American Medical Association is unable to carry on the campaign because of the following reasons: (1) by virtue of its charter it has been accorded the status of a non-profit, scientific and educational body; (2) it is exempted from income and social security taxation; (3) it must continue the many activities essential to the best interests of medicine and the public welfare under the present budget, and (4) because of legal reasons. The only organization available for this purpose is the National Physicians' Committee. The responsibility for a campaign to arouse public opinion in defense of organized medicine and the principles it stands for will have to be carried on largely by this organization. The N.P.C. has already accomplished a great deal in the defense of American Medicine, but its activities must be accelerated in order to assume the greater responsibilities which have now been thrust upon it.

It is obvious that funds will be necessary to carry on the campaign. It will be necessary to raise more than $100,000 among the physicians of America. Unless this can be done, its efforts cannot be effective. The trustees of the National Physicians' Committee look forward with confidence to the individual members of the American medical profession in supporting this objective. They believe that the members realize their responsibility in the present situation and will give as generously as they can toward furthering the campaign to influence public opinion. For this purpose there is no objection to enlisting the county medical society in our efforts to raise the necessary funds. A definite campaign to do this should be started at once. Each member of the medical profession in Minnesota will receive a circular from the national office of the N.P.C. which will explain the situation in greater detail. We would like to raise at least $10,000 in Minnesota. It is necessary to take immediate action—will you do your part?

W.F.B.

A MINNESOTA PLAN FOR THE CARE OF THE MEDICALLY INDIGENT

Much interest was expressed by medical association representatives all over the country in the papers presented at the Conference on Medical Service in Chicago by Mr. Walter W. Finke, Director of Social Welfare of Minnesota and Dr. A. W. Adson, chairman of the Medical Advisory Committee to the Division.

The general agreement was that Minnesota had stepped out ahead in the solution of the knotty problems of medical relief in rural areas. The paper presented by Mr. Finke is given here in full because it constitutes an official expression of policy which is of vital interest to all physicians. Dr. Adson's paper, slightly abridged to avoid duplication, is printed also as interesting evidence of the complete coöperation of his committee and the physicians of the state in the plan.

Mr. Finke: I acknowledge with appreciation the privilege of appearing on your program today. It is but natural that I approach with diffidence the presentation to a professional group of a topic which is fundamentally the concern of that group itself. I am encouraged to do so, however, by the fact that I am to share in this presentation with a distinguished member of your own profession, Dr. A. W. Adson, who, during the past year and a half, has served ably as chairman of the Medical Advisory Committee to the Division of Social Welfare of the State of Minnesota.

It is our mutual intention today to explain and discuss the very rapid developments of the past year and a half with regard to the medical care of those many people in our State who are, in one way or another, dependent for assistance on one of the many welfare programs now maintained by government. It shall be my province to discuss the general administrative aspects of the problem and to set forth and define the basic and fundamental principles which underlie our plan of operation. These points it seems quite logical for me to discuss since I represent the viewpoint of the administrator and, so far as the State of Minnesota is concerned, of government. Doctor Adson, who will shortly succeed me on this platform, will discuss the practical application and working of the program from the standpoint of the practitioner and the medical profession.

Now then, to a discussion of the matter at hand—

Welfare Patch Work

You are all of you familiar, I believe, with the patch-work growth of governmental welfare programs during the twirling thirties. Speeded by the necessity of meeting problems hitherto uncomprehended by government, there came into being a number and variety of welfare programs, each calculated to meet a part or segment of the total of human needs; some of these were spasmodic, some were strong enough to survive—with certain modifications, most were unrelated to the others at the time of their own conception. It was entirely natural, therefore, that we should soon reach a time when the urgent need was not for more specific welfare programs, but rather for a bringing together and adjusting of these semi-independent efforts within the confines of a sound and integrated pattern of social welfare. Recognizing this need, Minnesota—less than two years ago—created a unified division of welfare in the State government and placed authority for the supervision of all welfare programs in that one governmental department. Thus the first fundamental of progress in the administration of welfare programs in Minnesota has become that of *integration.*

Medical Implications

When this newly-created Division of Social Welfare started to function in July, 1939, there was created in its initial internal organizational structure a Medical Unit, headed by Dr. H. E. Hilleboe, a full-time medical man of highest professional standing, whose background includes not only extensive experience as a private practitioner but training in the field of public health as well. Hence it was recognized—and this is the second basic fundamental which underlies Minnesota's welfare program—that everyone of the individual welfare programs has a medical implication; that involved in each of those programs are numerous medical problems best solved by medical men; that in the conduct of every one of these medical programs there is involved, in some way or other, medical care for an indigent person; that, in essence, it is the composite of all of these elements which constitutes a program of medical care in the field of welfare.

Hence it is the function of the Medical Unit of the Division of Social Welfare to act in a threefold capacity. First, it conducts those direct medical programs for which the State assumes

responsibility, such as the program for crippled children, supervision of tuberculosis sanatoria, licensing of maternity homes and the like. Second—and fundamentally important—the Medical Unit has the responsibility of developing and directing a soundly conceived program of medical research—for certainly if we are to progress in this whole field of medical and institutional care, our emphasis must constantly be on research. Third, this Unit serves all state welfare programs insofar as problems of medical care are concerned and develops the modus operandi by which our relationship with the medical profession itself is established and maintained.

Basis Individual

Thus it is that in Minnesota, our program of medical care for the indigent is made up of a number of elements—the medical care given an old age assistance recipient which is included in his monthly grant; the medical care given to a dependent child, included in the aid to dependent children's grant of its mother; medical care given to a general relief recipient, or provided by supplementary relief grant to a WPA worker—all of these are elements of the total whole which we describe as our medical care program. Yet notice the important fact, namely, that in each instance, the medical care is given to the recipient on the basis of his being an individual and with relation to the implications of his individual and family problems.

I believe that the problem of medical care should be considered as an integral part of the total care to be given to an individual. I do not believe that the one item "medical care" should be isolated and set up as a thing apart—as something to be approached and handled on a regimented basis. I feel exactly the same way about all care which should be given to people in need. They must have food—yet I would not force them to go to a commissary for specified items. They must have shelter—yet I would not force them to live in a camp. They must have clothing—yet, within reasonable limits, they should have the right of selection of such articles. In the same way, all of these people should have adequate medical care—yet there should be free choice of physician on an individual basis and not the compulsion of reliance upon a specified practitioner.

Authority Decentralized

The third principle which underlies our plan of operation of welfare programs in Minnesota is that of the decentralization of administrative authority. It is necessary that this principle be briefly explained since Doctor Adson will shortly refer to the creation of county medical advisory committees. The purpose and nature of their existence is explained by our plan of decentralization of administrative authority.

I think it is now well agreed among those of us who are engaged in the administration of welfare programs, that the cost of these programs is too great in total to be borne by any one of the three levels of government—local, state or federal. Assuming, then, that there is a sharing of the costs of these programs, it is my belief that the soundest administration of the programs can be obtained by a decentralization of authority. That is, subject to the maintenance of minimum standards of operation and to the achievement of substantial uniformity throughout a State, the actual processes of administration should be placed close to the people who are to receive assistance from these programs. This makes possible individual attention; it brings into play local discretion and responsibility; and it avoids the sometimes unfortunate results of centralization of authority with its attendant inelasticity and mass approach to a problem. To further dwell upon this point is here not possible. However, let me simply say that, following this theory of governmental operation, the actual administrative authority for conduct of the welfare programs in Minnesota is vested in integrated county welfare boards, representative not only of elected officials, but also of lay members of the community. These boards conduct the programs under the general guidance and leadership of the State Division of Social Welfare which establishes minimum standards and sets up the general rules governing the welfare programs.

Advisory Committees Named

But one other fundamental remains to be discussed as a prelude to Doctor Adson's presentation. Having created a Medical Unit in the Division of Social Welfare, we immediately turned to the medical profession itself for assistance in guiding us in the conduct of the medical portion of our welfare programs. This was done upon the basis of our fourth fundamental. That is—

that the solution of medical problems in the welfare field should be found by working through and with the medical profession itself.

Proceeding upon this very sound assumption, I named a State-wide Medical Advisory Committee to work with the Division of Social Welfare. The membership of this committee was chosen from a panel of names submitted to me at my request by the Council of the Minnesota Medical Association. Doctor Adson was named Chairman by the committee itself. Ex officio members of the committee include the executive officer of the State Board of Health, the executive secretary of the State Medical Association, and the Chief of the Medical Unit of the Division of Social Welfare. This committee has met regularly throughout the past year and all medical policies relating to welfare programs are first submitted to the committee for its consideration and approval before adoption by the Division of Social Welfare. With the approval of this Committee, small technical sub-committees were established in the various specialties to work with the Division on problems arising in such fields as Tuberculosis, Ophthalmology, Orthopedics, Pharmacy, and Dentistry. Reports on the work of these technical subcommittees are made periodically to the general advisory committee.

At the suggestion of the State-wide Advisory Committee and the State Medical Association, county medical advisory committees were created in each county of the State to work in coöperation with local county welfare boards in handling—on the local level—medical problems which relate to the welfare programs. Whenever a medical bulletin relating to one of the welfare programs has been prepared by the Division of Social Welfare, and cleared through, amended and approved by the State-wide Medical Advisory Committee, this bulletin is then released by my office to the county welfare boards and at the same moment copies of the bulletin are released by the office of the State Medical Association to the county medical advisory committees.

Profession Assumes Responsibility

Thus the medical profession itself participates in advancing the program of medical care in the welfare field in Minnesota. Through these advisory committees, the profession recognizes its responsibility in providing a high standard of medical care to all of these people. It likewise recognizes that it must assume responsibility of controlling certain practices of its own members which may not be conducive to a continuing amicable relationship as between the welfare boards and the medical profession itself. Also, the profession has recognized the fact that funds are not unlimited and that the problem is to provide adequate medical care within the limits of funds available. Working side by side in this mutually advantageous and coöperative arrangement, the Division of Social Welfare and the medical profession of the State of Minnesota have succeeded in developing ways and means during the past year and a half of advancing our program of medical care. Throughout this period of time, we have proceeded upon the basis of the four fundamentals which I have outlined in this brief presentation. Let me review them briefly for you. They are:

1. The integration of welfare programs within the structure of government so as to eliminate confusion and clarify lines of administrative authority;
2. The recognition of adequate medical care as an essential element of human need, to be provided upon an individual basis with free choice of physician preserved;
3. The decentralization of administrative authority;
4. The solution of medical problems in the welfare field through and with the medical profession itself.

As an administrator, I can say in all sincerity that I am deeply indebted to the medical profession of my State for the rôle it has played in developing our program of medical care. As I look to the future, I have no fear of those problems that as yet remain unsolved in this field—I am confident in the thought that together with the profession we shall find the sound solution.

It is a pleasure now to yield the platform to Dr. A. W. Adson, chairman of the Minnesota Medical Advisory Committee.

Dr. Adson: The plans for rendering medical care to indigent and near-indigent patients differ for those who live within the larger cities and for those who live in the rural districts and smaller towns. The larger municipalities provide city hospitals for those that are indigent and those that are medically indigent. The expenses for such relief are financed from the city's relief

budget. However, this budget is supplemented by state relief funds. The economic status of patients seeking medical relief in the city hospital is determined by the department of social welfare of the respective hospital. Those that are considered eligible for medical treatment receive hospitalization and medical care gratis.

County System Best

The county and rural districts, containing towns and villages, operate on one of two systems: the county plan or the township plan. The county plan appears to work more efficiently than the township plan, since the county units operate through a welfare board and an executive secretary, while the township plan calls for less centralized organization and medical relief is approved by a greater number of authorized individuals, which permits of political interference. The medical relief rendered by the county plan is administered by one of three procedures. The first is the one in which the welfare board allocates a set sum for professional services, in which all of the physicians in the county participate on a unit basis, giving the clients the free choice of physician, hospital and medical bills being approved by the welfare board as they arise. The second procedure is one in which the medical client appeals to the executive secretary of the welfare board, who approves the relief and authorizes the patient to choose his physician, who decides the type of medical relief necessary and the amount of medical and hospital service necessary, bills being paid from the county welfare funds which are derived from county taxation and supplemental state aid from the state relief funds. The third procedure is the one in which the county welfare board hires a physician to render medical aid to those who are entitled to it. This last procedure has not proved satisfactory since patients are not given the privilege of choosing their physicians and too often the physician who accepts the position of county physician, whether well qualified or not, has more patients than he can properly care for.

Freeborn County Plan

The first procedure under the county plan has worked out more satisfactorily than the other two, since fewer conflicts between the patient and the welfare board have arisen. An illustration of the success of this procedure appeared in Freeborn County, in the state of Minnesota. The physicians of that county agreed to render professional services to indigent clients for the year of 1940 for the sum of $7,500 plus $1,000 to be used for drugs. At the conclusion of the year it was learned that the services rendered by the county physicians to these clients, on a fee basis of 60 per cent of their standard fees for general medicine was $500 in excess of the sum allotted. Members of the county welfare board were so pleased with the services rendered by the physicians, and the harmony among all involved, that they made up the difference and paid the county physicians the deficiency of $500. For the ensuing year the Freeborn County welfare committee has allocated $8,000 for professional services for the care of indigent clients. They have likewise agreed to approve hospital bills and medical supplies as they did in 1940, as authorized by the physicians of the county. They have also agreed to provide professional fees on a 60 per cent basis, hospitalization and medical supplies for the occasional indigent client who requires special medical treatment which is not obtainable in Freeborn County, providing that the local physicians approve the reference to a specialist outside of the county.

The fee basis for professional services is not a fixed one for all counties. However, 60 per cent of the average fee charged for the respective communities is the fee that is usually agreed on and dates back to the State Emergency Relief Administration plan, when state and federal reliefs became necessary. The medically indigent, those in the low income groups, and those who are employed under the Works Progress Administration, if they are unable to provide for their own medical care, must apply to the county commissioners for aid, as they are not entitled to medical relief from the local welfare board under the present statutes. The non-resident, or floater, finds himself in an embarrassing position, since he does not qualify for medical relief under the social welfare regulations, nor is the county obliged to assume the responsibility. Services that he receives must necessarily be donated by both physicians and hospitals.

Controversial Medical Problems

Although the State of Minnesota, through its director of social welfare and the welfare groups of the respective counties and its physicians has

developed adequate plans for providing medical care for indigent patients, controversial problems have arisen and still continue to arise, the most common of which are as follows:

1. Does the client need medical care?
2. How much medical care is needed?
3. Is hospitalization required?
4. What fee should be charged for professional services and hospitalization?
5. Who shall decide that medical care is considered an emergency?
6. Is the physician obliged to render a service gratis in a case of emergency when the client failed to secure an authorization?
7. How should physicians be controlled if they tend to administer excessive or unnecessary medical care?

Minnesota's department of administration through its director, Walter W. Finke, approached the Council of the Minnesota State Medical Association for advice. The plan developed with Council approval has been outlined by Mr. Finke.

The state medical advisory committee meets at the call of the director. The first order of business is to review the disposition of controversies presented at a former meeting and to offer resolutions when final disposition is needed. The next order of business is to review reports of the technical committees such as those on dental care, the crippled child, the tuberculous and the psychiatric patient. Following this, problems of state interest are discussed. These problems may have to do with choice of a physician who resides in the trade area but not in the county, county surveys concerning service and cost of medical care, the responsibilities of county commissioners with reference to medical needs in the low income group and changes in the state law to provide funds for professional services during the terminal illness of the aged who are receiving old age assistance.

Results

The following illustrations exemplify some of the results accomplished by the Minnesota plan of coöperation between welfare boards and physicians:

1. Complaint was made by a county welfare board which refused to pay for professional and hospital services for a medical relief client who chose as his physician one who resided in another county. It so happened that the relief client lived in another trade area than that of the county seat and his family physician was a resident of the adjoining county, which was but a few miles from the client's home.

It was decided that the patient was entitled to choose his own physician in the trade area, even though he resided in an adjoining county.

2. A county welfare board complained that a young physician entering the community suddenly found it necessary to operate on an excessive number of relief clients and thus objected to paying the professional bill. Following investigation, the state medical advisory committee recommended that the surgeon, complained of, submit his clinical, operative and pathologic records to the county medical advisory group. If they then found that his records were in order and the patients required surgical care, the bill should be paid. The investigation by the local medical committee cleared the surgeon of criticism and the bills were paid.

3. Complaints were made against a physician on the ground that he was submitting bills for obstetrical care when the patients failed to pay for services received. Investigation by the field representative, executive secretary of the state medical association, and Dr. Hilleboe, Chief of the Medical Unit of the State Division of Social Welfare, revealed that several of these patients were not true relief clients but were individuals who came within the low income group and were medically indigent. A compromise resulted in which the county commissioners agreed to pay a limited fee for those who came within the low income group and who were not entitled to relief from the welfare board.

Coöperation Gratifying

The coöperation between the state department of social welfare and the physician since the development of the Minnesota plan has been most gratifying. Although physicians are inclined to be skeptical of relief agencies as institutions attempting to dictate the procedures of medical practice, destroy the freedom of free choice of physician by the patient and at the same time expect physicians to render their service gratis, they have found this not to be true under the present state administration. Governor Stassen, through his director, Walter W. Finke, has invited the medical profession to help solve its own problems.

These public officials have recognized that medical relief of the indigent client is one of the essential reliefs that society must provide. They expect the medical profession to contribute in part to this relief but they also are willing to compensate the physician for the services rendered to the relief client in so far as funds have been provided.

FOR YOUR INFORMATION

(Monthly Editorial prepared by the Medical Advisory Committee)

Your Medico-Legal Advisory Committee believes it apropos at this time to place before you some of the legal aspects of the practice of medicine in the State of Minnesota, the knowledge of which may aid in preventing malpractice suits. The following excerpts are quoted from an address by Mr. Stan D. Donnelly, prominent Saint Paul attorney, who is particularly well-qualified in legal matters pertaining to the practice of medicine in Minnesota, and who has had a wide experience in the trial of malpractice suits:

"With respect to the legal aspects of the practice of medicine, the first thing to be borne in mind is that the law imposes a relation between a physician and his patient based upon contract. . . . . .

"Every physician, when he undertakes to diagnose, operate, or prescribe for a patient, enters into a distinct contractual relation with that patient. The law imposes upon the Doctor the duty of possessing that reasonable degree of learning and skill that is ordinarily possessed by physicians and surgeons in the locality where he practices, and which is necessary to qualify him to engage in the practice of medicine and surgery.

"He is required by law to use reasonable care and diligence in the exercise of his skill to accomplish the purpose for which he is employed. He is also obliged to use his best and honest judgment. . . . . .

"The law holds a physician liable for an injury to his patient resulting from want of the requisite knowledge and skill, for the failure to exercise reasonable care, or the failure to use his best judgment. However, it is unquestionably the general rule of law that the physician is not a guarantor of cures or good results in the absence of express agreement to that effect; he is not liable for a mere mistake of judgment if he honestly exercised his best judgment after careful examination and consideration of available information and facts in the situation with which he was confronted at the time.

"If the Doctor does not ascertain available facts and information prior to exercising his judgment he may be held liable as for negligence in case of mistake of judgment. . . . . .

"Another obligation imposed by law upon physicians and surgeons is that they keep abreast of the times. This does not mean that the physician or surgeon must be ahead of the times—it does not require him nor give him the right to experiment upon a patient—but it does mean that he must keep up with the times; in other words, know and use the generally approved methods of practice of the average skilled physician and surgeon in the community in which he is engaged in practicing his profession.

"It is a general rule of law to be applied in a malpractice suit against a physician or surgeon that he is not charged with possessing the highest degree of knowledge or exercising the highest degree of skill, the sort that is possessed by only a few in any business or profession, but he is required in a given case to have exercised the skill and learning of the average Doctor in his community."

Your Committee believes that the preceding information as to the legal responsibility of doctors in the practice of medicine will prove of value to the physicians in Minnesota. In future editorials further information along this line will be included.

Remember, that while illness is commonplace to the doctor, it is unusual to the patient.

Supreme Court Upholds Eight-Year Sentence of Saint Paul Osteopath

Re: State of Minnesota vs. Samuel M. Stern.

On April 10, 1941, the Supreme Court of Minnesota upheld the sentence of not to exceed eight years ordered by Judge Kenneth G. Brill of the Ramsey County District Court on May 13, 1940, for Samuel M. Stern, Saint Paul osteopath, who pleaded guilty to an information charging him with the crime of abortion. Stern was convicted of the crime of embezzlement on January 3, 1922, by a jury in Orange County, California. He served one year in the San Quentin prison and was then paroled. In September, 1938, he obtained a pardon from former Governor Merriam of California "in order to restore his citizenship." Stern claimed that having been pardoned by the Governor of California, he could not be given a double sentence by Judge Brill in the abortion case. However, the Supreme Court of Minnesota upheld Judge Brill and pointed out that the Legislature had not excepted pardoned prior criminal offenses from the habitual criminal law of this state, and, therefore, Stern was properly sentenced by Judge Brill to a term of not to exceed eight years at hard labor.

Stern was arrested in Saint Paul following the death of a twenty-one year-old Bemidji girl, who had been to his office for a criminal abortion. The investigation into that case disclosed that Stern had previously aborted another Bemidji girl and it was to this latter offense that Stern pleaded guilty. Stern's osteopathic license has since been revoked by the State Board of Osteopathic Examiners.

MINNESOTA STATE MEDICAL ASSOCIATION

88th Annual Session

May 26, 27, and 28, 1941

St. Paul, Minnesota

ANNOUNCEMENTS

Presiding officers at each session have been instructed by the Committee on Scientific Assembly to show a blue light on the speakers' rostrum two minutes before the end of each speaker's program time. A red light will show when his time is up. All meetings are in charge of committee members.

Register and Secure Your Badge at the Registration desk at the Saint Paul Auditorium at 8 a. m. Registration on Sunday, May 25, will be in the lobby of the Hotel Saint Paul.

Telephone Service: Special incoming lines have been installed at the Registration desk. All local and long distance calls will be handled promptly under the direction of Mrs. Nellie Grant Christenson, Physicians Exchange.

Bring Your Membership Card: There will be no registration fee for those who present a membership card or receipt or other evidence from their county society or the state association or the American Medical Association nor for members of associated professions including dentists, pharmacists, interns, nurses, hospital personnel, teachers or social welfare workers who present invitations or other identification.

Badges: You are requested to wear your badge while you are on the convention floor. This is important and will greatly assist us to eliminate undesirable persons such as cranks and pickpockets who so frequently try to take advantage of meetings of this character.

Woman's Auxiliary: Wives of physicians attending the meeting may secure programs of the business and social sessions of the Woman's Auxiliary at the Woman's Registration Desk in the lobby of the Hotel Saint Paul. All visiting women are cordially invited to attend the special events arranged by hostesses of the Ramsey County Medical Auxiliary. Among these is a tea at the University Club, Monday, May 26. Every Auxiliary member is invited to attend the Annual Meeting and luncheon Tuesday, May 27, at the Commodore Hotel, and all out-of-town guests are invited to attend a breakfast as guests of the Ramsey Auxiliary at 10 a. m., Wednesday, May 28, Hotel Saint Paul.

Automobile: Good parking space is available next to the Auditorium.

Luncheons: Twenty Round Table Discussion Luncheons have been arranged for Tuesday and Wednesday, May 27 and 28, at the Hotel Saint Paul. Tickets must be purchased in advance for these luncheons. Lists of subjects and leaders are printed in this program. Attendance at each luncheon is limited to 25 and late comers will be accommodated according to their choice if limits have not already been reached. Tickets 75 cents.

Annual Banquet: The annual dinner for members, guests and their wives will be held at the Hotel Saint Paul, Tuesday evening, May 27, at 6:30 p. m. Col. John R. Hall, M.C., Washington, D. C., Director of the Hospital Division, Surgeon General's Staff, U. S. Army, and B. J. Branton, President of the Minnesota State Medical Association, will be banquet speakers. Tickets $1.50 per person.

Surgery of Trauma, Tuesday: All day Tuesday, May 27, will be devoted to a special program on the Surgery of Trauma. The Great Northern Railway Surgeons' Association which holds its annual meeting concurrently in Saint Paul, will unite with the Minnesota State Medical Association for this program. All surgeons in this region of the Northern Pacific Railway Co., the Omaha Railway Co., and the Soo Line Railway Co. have been invited to attend and two of the distinguished guest speakers on this program, Thomas M. Joyce, of Portland, and Sumner L. Koch, Chicago, will appear through the courtesy respectively of R. C. Webb, chief surgeon of the Great Northern and A. W. Ide, chief surgeon, Eastern Division of the Northern Pacific Railway Company.

Other Guest Speakers: In accordance with an established precedent, several societies are also sponsoring visiting guest speakers for this meeting. We are indebted this year to the following societies:

The Minnesota Radiological Society—speaker, LeRoy Sante, St. Louis, who will deliver the society's annual **Russell D. Carman Lectureship** in radiology.

The Saint Paul Clinical Club—speaker, Edward D. Churchill, Boston.

The Trudeau Society—speaker, Henry C. Sweany, Chicago.

The Northern Minnesota Medical Association—speaker, Henry H. Kessler, Newark, N. J.

Northwestern Pediatric Society—speaker, Albert D. Kaiser, Rochester, New York.

Open House: All convention visitors and their wives will be guests of the Minnesota State Medical Association and the Ramsey County Medical Society at an Open House and **Gay Nineties Show** to be held Monday night beginning at 7 p. m. in the Arena of the Saint Paul Auditorium. Exhibits will be open for leisurely inspection and there will be music and a vaudeville show at 9 p. m., featuring lively entertainment of the nineties. Refreshments will be served.

Medical Women's Luncheon: The American Medical Women's Association, Minnesota Branch, will hold a luncheon meeting at the Saint Paul Women's City Club, Monday noon, May 26. All women physicians are invited. Make reservations in advance through Nellie N. Barsness, 540 Lowry Medical Arts Bldg., Saint Paul. Tickets 75 cents.

National Physicians' Committee for the Extension of Medical Service: Minnesota members and all other interested physicians are invited to attend a luncheon meeting of this committee on Monday, May 26, 12:15 p. m., at the Hotel Saint Paul. John M. Pratt, of Chicago, Executive Administrator, will speak. Tickets 75 cents.

Alumni Dinner: Minnesota Medical Alumni will hold their annual reunion at 6 p. m., Monday, May 26, in the Casino, Hotel Saint Paul. Clifton M. Utley, of Chicago, Director of the Council on Foreign Relations, will speak on "America in a World of War." Open to all members of the Minnesota State Medical Association and their wives. A buffet dinner will be served. Tickets at the Registration Desk, $1.50 per person.

Reunion, Class of 1901: Members of the Class of 1901, of the University of Minnesota Medical School, will hold their 40th annual reunion dinner at the Hotel Saint Paul, Monday, May 26, at 6 p. m., W. H.. Aurand,. Minneapolis, chairman. Tickets $1.50 per person.

Northwestern Alumni Reunion: Northwestern Medical Alumni will hold their annual reunion dinner at the Hotel Saint Paul, Monday, May 26, at 6 p. m., H. R. Tregilgas, South Saint Paul, chairman. Tickets $1.50 per person.

Minnesota Society for the Prevention of Blindness: The society will sponsor a dinner meeting, Monday, May 26, at the Hotel Saint Paul, at 6 p. m. Gaylord W. Anderson, Professor and Head of the Department of Preventive Medicine and Public Health, University of Minnesota, will speak on "Conservation of Vision." F. E. Burch, of St. Paul, will introduce the speaker and Mrs. Alfred Pillsbury, Minneapolis, president of the organization, will preside. Tickets $1.50.

Golf: The annual Golf Tournament of the Minnesota State Medical Association will be held Sunday, May 25, at the White Bear Yacht Club. This is a fine course and a beautiful place and all medical golfers are urged to enter the tournament. A special invitation is extended to Auxiliary members to play also this year. Registrations should be made in advance with J. F. Noble, Ancker Hospital, chairman. Attractive prizes have been donated for tournament winners.

GUEST SPEAKERS

Sumner L. Koch is Associate Professor of Surgery at Northwestern University Medical School and attending surgeon at Passavant Memorial and Cook County Hospitals.

Thomas M. Joyce is Professor of Surgery and Head of the Department of Surgery at the University of Oregon Medical School.

Edward D. Churchill is John Homans Professor of Surgery and Chief of the West Surgical Service at Harvard Medical School and Chairman of the Surgical Executive Committee at the Massachusetts General Hospital.

Walter M. Simpson is Director of the Kettering Institute for Medical Research and of the Diagnostic Laboratories at Miami Valley Hospital, Dayton, Ohio; Lecturer in Internal Medicine in the Ohio State University Medical School and Special Consultant to the U. S. Public Health Service.

LeRoy Sante is Professor of Radiology and Director of the Radiological Department of St. Louis University Medical School and Chief Radiologist at St. Louis City Hospital, and at St. Mary's Hospital and Infirmary, the Firmin Desloge Hospital and the Mount St. Rose Hospital for Tuberculosis.

Henry H. Kessler is attending orthopedic surgeon at Newark City Hospital, New Jersey, Newark Beth Israel and Hasbrouck Heights Hospitals, and the Hospital and Home for Crippled Children.

Albert D. Kaiser is Associate Professor of Pediatrics at the University of Rochester School of Medicine, Assistant Pediatrician at Strong Memorial Hospital and former Chief of the Pediatrics Service at Rochester General Hospital.

Henry C. Sweany, Medical Director of Research, Director of Laboratories of the Municipal Tuberculosis Sanatorium, Chicago.

Colonel John R. Hall, M.C., is the Director of the Hospital Division, Surgeon General's Staff of the U. S. Army, at Washington, D. C.

SCIENTIFIC PROGRAM

Saint Paul Auditorium

Monday, May 26, 1941

Morning Session

A. M.

8:00 Visit Demonstrations, Scientific and Technical Exhibits

8:30 **Scientific Cinema** .....**West Arena**
The Fundamentals of Technique for Acute Surgical Mastoiditis
L. R. Boies.....Minneapolis

9:00 Histamine in Clinical Medicine
B. T. Horton.....Rochester

9:15 Shock Therapy for Psychoses
G. H. Freeman.....Saint Peter

9:30 Toxemias of Pregnancy
C. J. Ehrenberg.....Minneapolis

9:45 Use of Protamine Zinc Insulin in the Treatment of Diabetes Mellitus: Practical Application
W. A. Stafne.....Moorhead

10:00 Survey of Postoperative Results Following Surgical Correction of retrodisplacement of the Uterus
M. O. Wallace.....Duluth

(Intermission)

10:15 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema .....**West Arena**
Surgical Diathermy for Cancer of the Face
G. B. New.....Rochester

11:00 Recognition of Coronary Disease
H. E. Richardson .....Saint Paul

11:15 The Place of Drugs in the Clinical Management of Coronary Disease
R. V. Sherman.....Red Wing

11:30 New Developments in the Diagnosis and Treatment of Brucellosis
Walter M. Simpson.....Dayton, Ohio
Director, Kettering Institute of Medical Research

12:00 Lunch

Afternoon Session

P. M.

1:30 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema .....**West Arena**
Thyroidectomy
Martin Nordland .....Minneapolis

2:00 War Injuries of the Chest
Edward D. Churchill.....Boston, Mass.
John Homans Professor of Surgery, Harvard Medical School

2:30 Use and Abuse of Vitamins
H. R. Butt.....Rochester

2:45 Relation of Emotional Disturbances to Disease
L. R. Gowan.....Duluth

3:00 Office Proctology
H. E. Hullsiek.....Saint Paul

(Intermission)

3:15 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema .....**West Arena**
Intracapsular Cataract Operation
Extracapsular Cataract Operation
F. E. Burch.....Saint Paul

4:00 Pathological Interpretations of Radiological Shadows in Pulmonary Tuberculosis
Henry C. Sweany.....Chicago
Medical Director of Research, Chicago Tuberculosis Sanatorium

Evening—7:00 P. M.

Open House—Gay Nineties Show
Arena, Saint Paul Auditorium

Music, Floor Show, Dancing, Refreshments. All convention visitors and their wives will be guests of the Minnesota State Medical Association and the Ramsey County Medical Society at an *Open House* and *Gay Nineties Show* to be held Monday night beginning at 7 p. m. in the Arena of the Saint Paul Auditorium. Exhibits will be open for leisurely inspection and there will be music and a vaudeville show at 9 p. m. featuring lively entertainment of the nineties.

Tuesday, May 27, 1941

Morning Session

Surgery of Trauma

A. M.

8:00 Visit Demonstrations, Scientific and Technical Exhibits

8:30 **Scientific Cinema** .....**West Arena**
Hypospadias: Surgical Treatment by the Inlying Graft Method
V. S. Counseller.....Rochester

9:00 Head Injuries
W. P. Ritchie.....Saint Paul

9:15 Eye Injuries
A. D. McCannel.....Minot, N. D.

9:30 Injuries to the Soft Tissues of the Neck
T. J. Kinsella.....Minneapolis

9:45 Penetrating Wounds of the Abdomen
G. I. Badeaux.....Brainerd

10:00 Physical Examinations in Industry
E. V. Goltz.....Saint Paul

(Intermission)

10:15 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema .....**West Arena**
Gastro-Enterostomy
J. M. Hayes.....Minneapolis

11:00 Twenty-five Consecutive Compound Fractures
Thomas M. Joyce.....Portland, Ore.
Professor of Surgery and Head of the Department of Surgery, Oregon Medical School

11:30 Primary Treatment of Wounds
Sumner L. Koch.....Chicago, Ill.
Associate Professor of Surgery, Northwestern University Medical School

12:15 **Round Table Luncheons..Hotel Saint Paul**
Rating of Hearing Loss
Henry H. Kessler.....Newark, N. J.
Acute Appendicitis
Thomas M. Joyce.....Portland, Ore.
Diagnosis of Tuberculosis
Henry C. Sweany.....Chicago, Ill.
Chemotherapy in Treatment of Wounds
Sumner L. Koch.....Chicago, Ill.

Injuries About the Knee Joint
H. B. Macey.....Rochester
Strabismus in Children
A. D. Prangen.....Rochester
Management of Nerve Injuries
W. T. Peyton.....University of Minnesota
Emergency Surgery of Trauma
A. W. Ide.....Saint Paul
Office Gynecology
W. A. Coventry.....Duluth
Eye Ground Examinations
V. J. Schwartz.....Minneapolis

Afternoon Session

P. M.
1:30 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema .....West Arena
Facial Plastic Surgery
J. J. Hochfilzer.....Saint Paul
2:00 Split Skin Graft for Dermal Repair
H. O. McPheeters.....Minneapolis
2:15 Treatment of Shock
G. C. MacRae.....Duluth
2:30 Blood Bank, Sera, Plasma
J. T. Priestley.....Rochester
T. H. Seldon.....Rochester
2:45 Rating of Disabilities
Henry H. Kessler.....Newark, N. J.
Attending Orthopedic Surgeon, Newark City and Crippled Children's Hospitals

(Intermission)

3:15 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema .....West Arena
One-Stage Resection of Right Colon: End-to-End Anastomosis
C. W. Mayo.....Rochester
4:00 **Russell D. Carman Memorial Lecture**
Roentgen Observations of Chest Injuries
LeRoy Sante.....St. Louis, Mo.
Professor of Radiology and Director of Radiology Department, St. Louis University School of Medicine
Introduction
H. M. Weber.....Rochester

Evening—6:30 P.M.

Annual Banquet .....Hotel Saint Paul
Presiding: J. F. Borg, President, Ramsey County Medical Society
Introduction of Mrs. J. J. Ryan, Saint Paul, President, Woman's Auxiliary
Presentation of Southern Minnesota Medical Association Medal
Presidential Address: B. J. Branton, President, Minnesota State Medical Association
Address: Col. John R. Hall, M.C., Washington, D. C., Director of the Hospital Division, Surgeon General's Staff, U. S. Army.

Wednesday, May 28, 1941

Morning Session

A. M.
8:00 Visit Demonstrations, Scientific and Technical Exhibits
8:30 **Scientific Cinema .....West Arena**
Foley Y-Plasty, an Operation for Stricture at the Ureteropelvic Junction
F. E. B. Foley.....Saint Paul
9:00 Chemotherapy in Pneumonia
W. W. Spink.....University of Minnesota
9:15 Chemotherapy in the Treatment of Streptococcal Infections
W. E. Herrell.....Rochester
9:30 Chemotherapy in Acute Purulent Otitis Media and Mastoiditis
J. F. Curtin.....Minneapolis
9:45 The Present Status of the Newer Endocrine Therapy
M. H. Hoffman.....Saint Paul
10:00 **Installation of officers**

(Intermission)

10:15 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema .....West Arena
Hemorrhoidectomy: Dissection Method
W. A. Fansler.....Minneapolis
11:00 The Rôle of Tonsils and Adenoids in Respiratory Infections
Albert D. Kaiser.....Rochester, N. Y.
Associate Professor of Pediatrics, University of Rochester
Discussion opened by
Irvine McQuarrie.....University of Minnesota
11:45 Alcoholism as a Neurosis
G. R. Kamman.....Saint Paul

12:15 **Round Table Luncheons..Hotel Saint Paul**
Chemotherapy
W. W. Spink.....University of Minnesota
W. E. Herrell.....Rochester
Non-Tuberculous Diseases of the Lung
H. C. Hinshaw.....Rochester
Proctology

Meeting of January 8, 1941

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town & Country Club on Wednesday evening, January 8, 1941. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p. m. by the President, Dr. John Armstrong.

There were forty-one members and two guests present.

Minutes of the December meeting were read and approved.

Dr. Armstrong expressed his appreciation to the members for the honor shown him in electing him as President for the coming year.

There being no old or new business to come before the Academy, the scientific program followed.

Dr. James A. Johnson, of Minneapolis, retiring President, read his Presidential Address. Numerous lantern slides were shown.

DIVERTICULA OF THE ALIMENTARY CANAL

James A. Johnson, M.D.
Minneapolis, Minnesota

I realize the subject of diverticula of the alimentary canal is rather extensive, and that I could well have confined myself to diverticula in a more restricted locality. The entire alimentary canal, however, is of similar anatomical construction and subject to the same defects, and I have, therefore, chosen to consider it as a whole.

The alimentary canal is composed of three layers of tissue to the diaphragm and has a fourth serous coat added in the abdomen. The arrangement varies somewhat with the function that it has to perform, but the same general tissue structure persists. They are the mucous or inner lining, the areolar or submucous, the muscular (largely arranged in circular and longitudinal fibres), and the serous or peritoneal layer within the abdomen.

A diverticulum can here be defined simply as a pouch or pocket leading off from the main tube of the canal.

Various classifications have been given for diverticula. I prefer here to make a simple division: (1) the true or congenital diverticulum, composed of all of the coats of the canal; (2) a traction diverticulum due to adhesions to the outside wall; and (3) the false or acquired diverticulum consisting largely of the mucous and submucous layers. The latter is by far the most common and consists of herniations through some defect in the canal, either congenital or acquired by weakening of the wall by disease. It is, therefore, not uncommon to find diverticula in more than one area of the canal at the same time.

Diverticula occur with regularity in definite locations throughout the alimentary canal. At first they were recognized only at postmortem examination, and later during operative procedures. During the past twenty years there has been constant improvement in roentgenological examination of the alimentary canal, and each year an increasing number of diverticula has been recognized, until now they should be of universal interest and importance to the medical profession.

Shiflett, in a routine x-ray examination of 768 stomachs and 887 colons found forty-four diverticula in the colon (4.96 per cent), thirty-three in the duodenum (3.74 per cent), six in the esophagus (0.79 per cent), five in the stomach (0.65 per cent), and only one in the small bowel. The relative frequency was colon, duodenum, esophagus, stomach and small bowel. This in general has been the experience of other observers. As to sex, they are of about equal incidence. Although they may occur at any age, it is usually during mid-life when patients seek relief. This is especially true of the acquired type, since they develop slowly and do not produce disturbances until they have reached sufficient size.

The etiology is either congenital or acquired. The congenital are due to embryologic remnants—as for example Meckel's diverticulum. The acquired occur from herniations either through anatomical defects or weakened areas in the wall as a result of disease, or from adhesions of surrounding structures to the outer wall of the canal producing tractions.

The symptoms in general depend upon the location and structure of the diverticulum. It may be present for many years without causing any trouble. The disturbance is largely due to retention of the contents of the canal, or an infection within the pouch. These naturally vary in different localities, and it will, therefore, be necessary to consider each area separately.

Esophageal Diverticula

There are two varieties of diverticula occurring in the esophagus; those that are due to pressure from within—the pulsion type of diverticula, and those that are due to traction from without—the traction diverticula. About 90 per cent of all diverticula in the esophagus are of the pulsion type and occur most commonly between the ages of fifty-five and sixty. They are due to a weakness in the posterior wall of the pharynx at a point where the cricopharyngeus and inferior constrictor muscle fibres meet. At this point there is a weak locality which is just posterior to the cricoid cartilage. Through this opening gradually occurs the herniation of the mucous and submucous layer of the posterior wall of the pharynx. The bolus of food constantly strikes against this area when swallowed, and a herniation of the mucosa and submucosa gradually takes place. At first, directly back, and later as the sac enlarges, it usually appears on the left side of the neck; rarely on the right.

The symptoms depend upon the size of the sac. At first, when it is small, there may be only chronic irritation and a dry unexplainable cough. Later, as it enlarges, there is regurgitation of undigested food, a gurgling sound on swallowing due to the air taken into the sac, often a sour odor to the breath; and later when the sac becomes very large and pulls upon the esopha-

gus, there is constriction with inability to swallow solid food and gradual loss of weight. When the sac is very large and causes pressure, there is at times marked dyspnea.

The diagnosis is made by x-ray examination, which demonstrates clearly the retention of the opaque mixture directly behind and below the pharynx. If the picture is not typical, the differential diagnosis should be made with the esophagoscope, since a cicatricial or compression stenosis of the upper part of the esophagus may produce a similar picture from the dilatation which occurs above. A perforation of the posterior wall of the esophagus which has allowed the opaque mixture to gravitate into a pocket may also produce a similar picture.

Treatment will depend somewhat upon the size of the sac. If it is small, dilatation of the esophagus below may give relief for a considerable time. However, all sacs continue to enlarge and most patients will require operation sooner or later. The chief danger in the operation is the descending infection along the fascial and muscle planes of the neck down into the mediastinum. There are two plans of surgical removal; first, the so-called two-stage operation, which is still advocated by most surgeons. The first stage consists of dissecting out the diverticulum through a tranverse or longitudinal incision in the neck. It is then brought up into the wound and placed high so that it tends to empty itself and no food can regurgitate into it. Gauze is then packed below it to produce adhesions, which at a later stage will have walled off the mediastinum so that there is no danger of leakage. At the second stage, one week to ten days later, the wound is again opened. The sac is tied off at its junction with the esophagus and resected, or in some instances removed without ligation, in which case a fistula will persist for a while but gradually close.

In October, 1937, Lahey reported eighty-two cases in which this method of operation was employed with only one death, which was due to uremia and not to any failure of technique. In discussing Dr. Lahey's paper, Dr. Thomas Shallow and Dr. W. Wayne Babcock contended that the one-stage operation was just as safe and would give better anatomical and functional results. Dr. Harrington of Rochester advocated the one-stage for the small diverticula, and in general, the two-stage for the very large diverticula. Hollinger and Jackson advocate placing the esophagoscope into the diverticulum, aspirating its contents, using the scope to light up the diverticulum during its dissection from the neck, and then elevating it into the wound. The scope is then introduced into the esophagus proper, the diverticulum is removed, and the hernia of the esophagus is repaired over the scope to obviate any stricture. There is no doubt that this type of operation is more accurate and gives a direct surgical repair of the hernial opening. For the average surgeon the two-stage operation is probably the safest.

Diverticula occur at or just above the bifurcation of the trachea. They are usually the result of traction by adhesions of inflammatory glands in the mediastinum. The mouths of these diverticula are usually large and as a rule do not retain any material but empty freely into the esophagus. Not infrequently a dilatation of the esophagus below the diverticulum is required. If they become very large, which seldom occurs, Hollinger suggests that they can be relieved by compression with artificial pneumothorax. They seldom require operation, which is fortunate because the risk is very great in this particular locality. The supradiaphragmatic diverticulum is relatively rare. At a point just above the diaphragm there is often a weak spot in the esophagus. When a spasm of the cardia occurs, there may be a herniation of the wall at this point. Unless the sac is large, the condition is usually relieved by dilatation of the cardia. If the sac is large, it can be sutured upright along the wall of the esophagus, or if feasible, an anastomosis of the diverticulum to the fundus of the stomach can be made.

Diverticula of the Stomach

Diverticula of the stomach are comparatively rare. Lay Martin in 1936 in the Annals of Internal Medicine states that since 1920 he found five cases in the records of the Pathological Department at Johns Hopkins University and Hospital, and another additional case discovered by x-ray examination. He made an exhaustive research of the literature and says that the first case apparently was discovered by Baillie in 1793, and since that time he was able to find ninety-two additional cases of pulsion diverticula which he carefully tabulated. Two of these were found in embryo and one in a four-month old infant. Most of them occurred in mid-life. Fifty-four of the 103 cases were women.

Shiflett in 1937 made a clinical analysis of forty-three cases collected from the literature and reported five personal cases. He concluded that the incidence was about .50 per cent. Eusterman and Balfour state that there had been fourteen proven cases at the Mayo Clinic prior to 1935, in ten of which surgical removal was accomplished, four having been recognized at postmortem examination. Diverticula of the stomach can be divided into three types: (1) the congenital or true diverticulum which consists of the entire wall of the stomach; (2) the pulsion type which results from herniation through some weakened portion of the muscular wall; (3) the traction diverticulum which is due to adhesions to the outside of the stomach wall. The most common location is at the cardiac end of the stomach, where the musculature is less developed. Of the 103 cases of pulsion diverticula collected by Lay Martin, 61 per cent were at the cardiac area while 39 per cent were distributed along the lesser curvature, either on the anterior or posterior wall. The average size was 1 to 6 cm., although a few were considerably larger.

The histology depends upon the type of diverticulum. The true or congenital type has the entire stomach wall. The pulsion or herniation type is represented only by the mucous and serous coats. Martin found a pancreatic rest or nodule at or near the tip of the diverticulum in fourteen of the 103 cases collected.

The symptoms are often lacking or consist only of mild gastric distress of an indefinite nature. When the sac retains the contents of the stomach or becomes infected, there is gastric distress with a burning pain

high up in the left epigastrium under the rib margin. A case of ruptured diverticulum has never been reported. In some cases there is eructation of food and occasionally vomiting.

The diagnosis is made by x-ray examination, but this can be done only when the barium is admitted and retained in the pocket. No doubt, therefore, many are overlooked, especially when there are no localizing symptoms. In carrying out the treatment, it is first necessary and very important to exclude all other lesions that could produce the existing symptoms. Secondly, after an exclusion of other lesions has been made and it is definite that the symptoms present are due to the diverticulum, all cases should first have thorough and careful medical management by a properly selected diet, antispasmodics and acid neutralization when necessary. Occasionally postural relief is obtained. Operation should be advised only when it is definitely established that the diverticulum is the cause of the symptoms and after careful medical treatment has been instituted. As an illustration of the above condition, I would like to report the following patient operated upon by me on March 11, 1940, the case having been previously reported in the Nicollet Clinic Bulletin for April, 1940.

Fig. 1. Mrs. C. H. Diverticulum of the posterior wall of the stomach near the esophageal opening.

Mrs. C. H., aged forty-nine, began to have epigastric pain with regurgitation of food and vomiting in 1921. An x-ray study at that time had revealed a pouch in the upper part of the stomach. An exploratory laparotomy had been done in 1924 and the surgeon reported to her that the stomach was adherent to the posterior body wall. The adhesions were freed and she was relieved of her gastric symptoms for about ten years. In 1935 she again began to complain of pain directly after eating. Regurgitation of food with occasional vomiting occurred. The pain was severe, of a burning character, and located high in the left epigastrium under the rib margin. She was unable to eat any food without distress. She had lost considerable weight. The physical examination was essentially normal except for an aortic stenosis which had apparently followed a severe attack of rheumatic fever at about the age of twelve, and was now producing some shortness of breath on exertion. The blood, urine and gastric contents were all normal.

X-ray study of the gall bladder revealed normal function and no evidence of stone. Roentgenological examination of the gastro-intestinal tract revealed a diverticulum on the posterior wall of the stomach high up near the cardiac end. The diverticulum retained the barium at the end of twenty-four hours and there was considerable local tenderness directly over it. The rest of the stomach and duodenum was normal. She was admitted to the hospital on February 22 for medical treatment of this condition. While resting in bed in the hospital, dietary, medicinal and postural attempts were of no avail. There was no relief of the epigastric distress. The cardiac condition by this time seemed much improved. An operation was, therefore, decided upon.

On March 11, 1940, she was operated on. The posterior wall of the stomach was explored and a diverticulum found close to the greater curvature and just below the esophagus. Under traction it was about 3 inches long and considerable narrowing was present near its entrance to the stomach. The walls of the diverticulum consisted of mucosa, submucosa and serosa. There was no muscular layer and no evidence of a pancreatic rest. The postoperative convalescence was normal and since her operation she has been relieved of her epigastric distress and is able to eat in a normal way. However, she still complains of some dyspnea which is due to her cardiac condition.

Diverticula of the Duodenum

Edwards in his recent work on diverticula of the intestine states that the first case of a duodenal diverticulum was reported in a pathological specimen in 1710. Prior to about 1920 there were only scattered reports in the literature. Many of them were found in pathologic specimens. During the past twenty years a wide interest has developed in this condition, mostly as a result of improved roentgenological diagnosis in this locality. The incidence now on routine roentgenological examination is about .75 per cent. The average age is fifty to sixty years. It appears about equally in both sexes.

Duodenal diverticula from an etiological standpoint can be classified into three types.

1. The ulcer type occurs in the first part of the duodenum and is the result of an ulcer scar, which causes a weakening of the wall or in some instances a narrowing of the opening so that by intraluminal pressure a pouch appears on the outside. This pouch is a herniation of all the layers of the duodenal wall.

2. The pulsion type is due to a weak spot in the muscle wall as a result of the entrance or exit of the bile and pancreatic ducts, or the openings through which vessels pass, or occasionally a pancreatic rest. Through these weakened areas in the muscular wall a herniation of the mucosa and the submucosa takes place. These occur on the lesser curvature in the second and third part of the duodenum.

3. The traction type results from adhesions to the

outer wall of the duodenum and produces a pouching of the wall by its traction. This is comparatively rare.

There are no typical symptoms of a duodenal diverticulum. Many, having never produced symptoms, are discovered on routine x-ray examination. It is only when the pouch retains the material or becomes infected that localizing findings occur. Symptoms may suggest almost any upper abdominal lesion.

The diagnosis is made by x-ray examination, and the diverticulum will be found only when the barium is admitted and retained in the pouch. When there is infection present, a localized tenderness may be noted. A diverticulum occurring about the pancreatic and bile ducts may by its pressure sometimes produce jaundice.

In considering treatment, it is first necessary to rule out by careful examination all other lesions that could produce similar symptoms in this locality. Secondly, nearly all duodenal diverticula will respond to medical treatment. It is only when constant retention is found in the pouch, when there is repeatedly definite tenderness over the pouch, either due to retention of material or inflammation, that operation should be considered. As an illustration, I would like to report the following case.

Mrs. H., aged eighty-five, came to the office for examination in April, 1937, complaining of almost constant distress, pain and soreness in the epigastrium. Occasionally she would vomit several hours after a meal. Previously she had been operated upon for cystic disease of the breast, for fibroids of the uterus, and an inguinal hernia. She had had a questionable heart attack about a year ago and was kept in bed for several weeks. On physical examination the heart was found to be normal in size. Electrocardiogram showed evidences of early myocardial damage. The blood pressure was 174 systolic and 90 diastolic; blood and urine were normal. X-ray study of the gall bladder revealed normal function with no evidence of stone. The stomach was likewise normal. However, there was a large diverticulum in the third part of the duodenum which at the end of twenty-four hours retained barium and was quite sensitive to pressure at the time of examination. She was confined to the hospital for some time on a low residue diet, antispasmodics and postural treatment without any relief.

On May 25, 1937, she was, therefore, operated upon. In the third part of the duodenum just to the right of the mesenteric vessels on the posterior and upper aspect of the duodenum was a diverticulum about 2 by 1.5 inches. It had herniated through the wall and the index finger could be passed through the opening into the bowel. The duodenum was completely mobilized from below upward without disturbing the circulation above and the adjacent pancreas. The sac was then tied off and the hernial opening in the muscle repaired. On examination there were no other lesions in the abdomen. The diverticulum consisted of mucosa, submucosa and a few muscular fibers. On examination October 26, 1937, nearly seven months after her operation, she stated that she was entirely relieved of her digestive symptoms. On x-ray examination a normal duodenum was found and there was no evidence of any local tenderness.

Diverticula of the Small Intestine

There are two types of diverticula of the small intestine: (1) the pulsion or herniation type; (2) the congenital or Meckel's diverticulum. The pulsion diverticulum is almost entirely confined to the jejunum. As a rule it is only found in the ileum when the entire small intestine is involved. According to Guthrie and Brown, the first case was reported and described by Sir Astley Cooper in 1844, when he found pouches in the

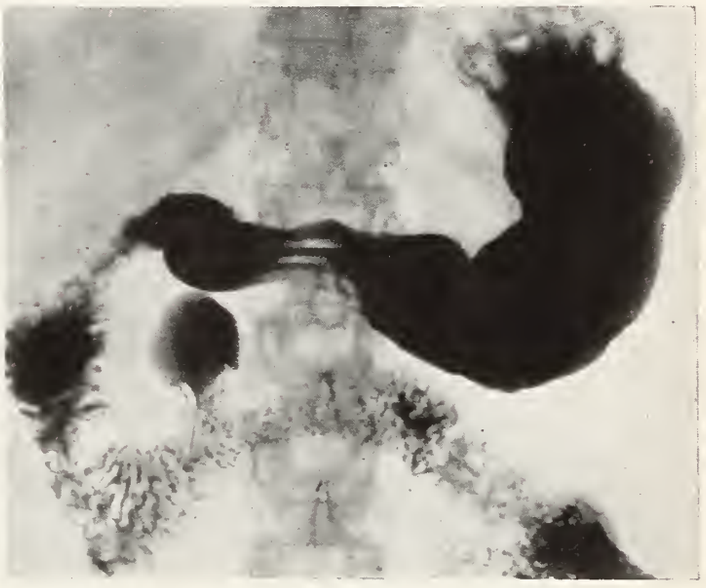

Fig. 2. Mrs. H. Large diverticulum of the third part of the duodenum.

proximal portion of the small intestine in a postmortem examination. The first roentgenological diagnosis was described by Case in 1920. They further state that it is probably present in about .50 to .10 per cent of routine roentgenological examinations of the gastro-intestinal tract. Rankin and Martin estimated that it would be found only once in every 25,000 routine roentgenological examinations of the gastro-intestinal tract. It is the least frequent location in the alimentary canal for diverticula. Edwards collected sixteen cases in a period of twelve years at Kings College Hospital in London: eight were found at postmortem, four at operation, and four on x-ray examination. The average age was 55. Nine were in men and seven in women. Hubeny and Pollack stated that since 1934, twenty-nine cases were reported: six found on x-ray examination, seven by operation and fifteen at postmortem.

The etiology has been well established and illustrated by Edwards and others. They herniate through a weak area in the intestinal wall and occur with regularity on either side of the mesentery, where the blood vessels perforate the muscle coats. Later, as they enlarge they may fuse from either side and join to form a large diverticulum in the mesentery. The pressure from within the bowel causes a herniation of the mucosa and submucosa through these weakened areas.

The symptoms from small diverticula are unimportant. However, when they enlarge, to retain the contents of the intestine, or become inflamed, there is epigastric distress together with nausea and occasional vomiting. Hemorrhage, perforation or, if the diverticulum becomes large enough, obstruction may occur, especially by a volvulus.

The diagnosis is made by x-ray examination and can only be made when the diverticula are large enough to admit the barium and especially to retain it.

In the treatment it is necessary here, as it was in

gastric and duodenal diverticula, to rule out all other lesions in the upper abdomen which might produce the given symptoms. If the diverticulum is small and does not constantly retain material and becomes infected, the patient will usually do well on medical treatment. It is only when symptoms persist after careful medical treatment or when complications such as perforation and obstruction occur that operation is necessary. If the diverticulum is single, it can be resected here as elsewhere. They are usually multiple, however, and in that case the area involved must be entirely removed.

Meckel's diverticulum is an embryologic remnant of the omphalomesenteric duct. When the embryo is about five weeks old, the duct has no further function and normally disappears. In about 2 per cent of persons, however, some form of remnant of this duct remains. In 1822 Meckel first accurately described its embryologic origin and the disease to which it was subject. Meckel's diverticulum is usually found in the lower ileum about 1 to 3 feet from the ileocecal junction. It has a great variety of sizes and shapes and its distal end is often attached to the abdominal wall at the umbilicus, either by a remnant of its obliterated portions or by the obliterated omphalomesenteric vessel. For some unknown reason it occurs three times as often in men as in women. It produces no typical signs or symptoms and its presence is usually recognized at the time of operation, although an occasional case has been found on x-ray examination. Meckel's diverticulum may become inflamed like an appendix and give rise to much the same symptoms. When the abdomen is opened for an acute appendicitis and the condition of the appendix does not explain the symptoms, the lower ileum should always be examined for the possible presence of a diverticulum. Occasionally it contains foreign bodies. One such case was reported before this Society in 1932 by Dr. Archa Wilcox, in which a fishbone had lodged and penetrated the walls to cause the inflammation. The most common disturbance, however, is acute intestinal obstruction.

In December, 1922, I described the mechanism of this before the Minneapolis Surgical Society and reported three cases. In May, 1932, I reported an additional case of acute intestinal obstruction due to Meckel's diverticulum before this Society. It is estimated that Meckel's diverticulum accounts for about 3 to 4 per cent of all cases of acute intestinal obstruction. There are a great variety of ways in which the obstruction may be brought about. First, when the diverticulum is attached to the abdominal wall, it may by its traction cause an angulation at its junction with the intestine, or the intestine being suspended in this way may rotate on a fixed point, causing the volvulus, or the loop of free bowel may twist itself about the cord attached to the diverticulum. Secondly, when there is a long diverticulum or a cord is attached to its tip, floating free in the abdomen, it may become adherent to another loop of bowel or to the mesentery or omentum, thus forming a band underneath which a portion of the bowel has become strangulated. Meckel's diverticulum is not an infrequent cause of intussusception in children. This occurs usually by the diverticulum being inverted into the lumen of the bowel, and then being pulled forward by the peristalsis. In one of my patients this resulted from the tip of the diverticulum becoming adherent to the outer wall of the intestine and then being caught by the peristaltic wave in such a way as to produce the intussusception. Meckel's diverticulum has a greater potential danger than the appendix and should be removed if found during the course of an abdominal operation.

Diverticula of the Colon

Incidence.—The colon is the most common location for diverticula in the alimentary canal. Ochsner and Bargen state that in 2,984 patients examined roentgenologically by barium enema, 7 per cent had diverticulosis. It was uncommon before the age of forty, most common between the ages of sixty-five and seventy-five. They were least common in the right colon and most common in the sigmoid flexure. Edwards states that in thirteen and one-half years, 2,139 examinations of the colon by barium enema were made at Kings College Hospital, and that 16.08 per cent over the age of thirty-five were found to have diverticula. He believes, however, this incidence to be high because all of these patients were examined because of colon symptoms. The average age was fifty-nine and it was found to be equal in both sexes. Shallow reports that diverticula occur in about 5 per cent of colons examined roentgenologically by barium enema over the age of forty, and that about 12 to 15 per cent of these develop diverticulitis. Most observers agree that it is of about equal incidence in both sexes, but that diverticulitis and its complications occur most frequently in men.

Etiology.—It has definitely been established by Edwards, Dixon, Deuterman, Weber and others that diverticula of the colon are due to herniation of the mucosa through the musculature of the bowel, where it is weakened by the entry of its vessels. The location of the diverticula corresponds to the entry of the vessels and also the site of the appendices epiploicæ. It is only in the severest cases, and then rarely, that the diverticula penetrate through the logitudinal muscle bands. They occur as the result of intraluminal pressure which pouches the mucosa through the weakened area, and they consist of the mucosa surrounded by a very thin layer of muscle fiber. At first such herniations are small, but they constantly tend to enlarge and become sacculated so that the pouch is often bottle-shaped with a narrow opening into the bowel. When they have arrived at this stage, they retain bowel contents and become infected, causing a series of complications.

The symptoms of uncomplicated diverticula usually consist of vague bowel disorder, much the same as we ordinarily attribute to a spastic colon. The diagnosis is made by roentgenological examination with barium enema. In the early stages they appear as irregular indentations between the haustra. Later they can be recognized as sacculations often with a narrow opening, and when the enema is expelled, show retention of the barium.

The treatment in uncomplicated diverticula is directed largely toward preventing complications, and consists of a low-residue diet together with liquid petro-

latum to soften and regulate the stool. Antispasmodics are frequently required. Regular habits, mental and physical hygiene are important. Anyone who has diverticula of the colon should be warned of the possible complications so that he may properly appreciate the

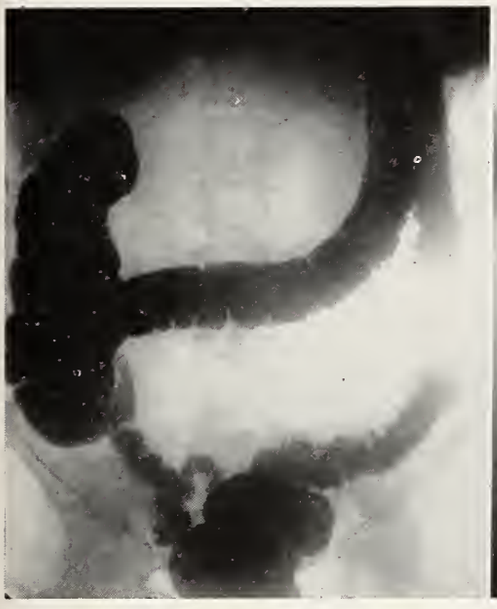

Fig. 3. Diverticula of the descending colon and sigmoid. This patient has had repeated attacks of mild uncomplicated diverticulitis.

Fig. 4. Peridiverticulitis of the descending colon with constriction simulating carcinoma. Operated upon August 19, 1940.

Fig. 5. Advanced diverticula of the sigmoid colon with repeated attacks of diverticulitis resulting in a mass in the pelvis and repeated temporary obstruction.

treatment to avoid them, and if they occur, to seek early medical consultation. The complications are due to various degrees of inflammation of the diverticula and are the main issue and danger to be considered. For the sake of clarity they can best be classified in accordance with the pathologic changes which occur and disturbances each of these produces.

1. *Uncomplicated diverticulitis usually of a mild recurrent type.*

This condition is no doubt more common than is generally recognized. It is not infrequently looked upon as a spastic colon, and often produces much the same symptoms, except that it is more severe, especially as to pain and constipation, and it is also recurrent. The pain is often severe and is usually located in the lower abdomen, especially on the left side. It is not infrequently mistaken for other acute abdominal lesions, especially in the pelvis. During the attack, especially if there is fever and a good deal of pain, there should be no attempts at roentgenological diagnosis with barium enema, since the pressure of this may cause a perforation. I have seen two such instances. During the attack such patients, especially if there is fever, should be kept in bed, have heat to the abdomen and sedatives to relieve pain. The diet should consist of liquids until the attack has passed. These patients usually remain quite well on careful medical management but are constantly subject to attacks when they overindulge in forbidden foods or become indiscreet in other activities. Some of these in time develop the more serious complications.

2. *Diverticulitis with peridiverticulitis.*

This is a more advanced condition in which the inflammation involves a localized area and has spread to the wall of the bowel and often causes a constriction, either partial or complete. The sigmoid is the most common location, but the transverse and descending colon is occasionally involved. Not infrequently such cases are mistaken for carcinoma. This was especially true before roentgenological diagnosis had arrived at its present perfection. There is still an occasional case where a questionable roentgenological opinion has to be given, and an exploratory laparotomy has to be undertaken in order to prove the condition.

On August 19, 1940, I operated, for example, on a woman aged sixty-seven who was in other respects very well. She had complained of attacks of pain over the midportion of the descending colon for the past five years. During the three weeks previous to her admission the pain had been especially severe and she had had increasing constipation. The x-ray showed a constriction in the descending colon just above the sigmoid. There was a diverticulum above and below this constriction. It was diagnosed roentgenologically as a probable carcinoma. At operation the mass on examination could not be distinguished from a carcinoma. It was, therefore, resected by a two-stage Mikulicz's operation. The pathological diagnosis was an inflammatory mass due to peridiverticulitis. She has had complete relief from all of her symptoms from which she suffered during the past five years.

In the sigmoid where the diverticula are larger and more numerous, a large mass often develops. Here usually there is a great deal of inflammation and the tumor mass becomes fixed in the pelvis. Partial or complete obstruction often develops, and not infrequently requires a colostomy. Some of the severest cases may have to be content with a permanent colostomy, but most of them can later be closed after the involved

area has been given a complete rest and irrigated to clear up the inflammation. It is certain that no attempt should be made to remove the area involved except when the inflammation has subsided and it is high enough to do a two-stage resection safely.

3. *Diverticulitis resulting in perforation.*

This is the most serious complication of diverticula and often requires a great deal of judgment on the part of the surgeon. Here experience is of paramount importance. It is necessary to consider two types of cases.

(a) The acute perforation directly into the peritoneal cavity.

This fortunately is comparatively rare because in most cases there has been previous inflammation and a walling off. However, occasionally an acute perforation occurs, which as a rule is quite dramatic and requires immediate operation, just as in gastric or duodenal perforation. If possible, the perforated area should be brought outside the abdomen like a colostomy. If this cannot be done, the perforation should be covered by omentum and a drain placed over the area involved. It is usually inadvisable and often quite impossible to close the perforation. There is usually so much inflammation and edema around it that if an attempt is made to close it, often more harm than good is done. A colostomy above the perforation should be done.

(b) The perforation resulting in a localized abscess.

If there have been previous attacks, one is fairly safe in assuming that a localization will occur. It is important here not to "rush in" but to wait until a localized abscess has formed. Such abscesses occasionally remedy themselves by draining back into the bowel, but in most cases drainage through the abdomen is necessary. Here it is best to be conservative and not to hurry, and it often requires considerable courage on the part of the surgeon to wait for the proper time.

4. *Diverticulitis resulting in an internal or an external fistula.*

A diverticulitis area may become adherent to adjacent structures into which it perforates and either a temporary or permanent fistula may result. The most common location is between the sigmoid and the urinary bladder. In fact, one might say this is not an uncommon complication. When such a perforation takes place, a colon bacillus cystitis at once develops which must be given immediate attention. Next, it is usually necessary to do a colostomy and follow this by irrigating the involved area of inflammation. After the inflammation has entirely subsided, the fistulous opening in the bladder can be closed with safety. The involved diverticulous area in the bowel can then be resected in the same way as a carcinoma. Occasionally the involvement is so extensive or so low down in the sigmoid that it cannot be resected. In such instances a permanent colostomy is the only alternative.

I have observed one instance in an old person over a period of many years, where the fistula has acted as a safety valve for recurrent attacks of diverticulitis in the sigmoid. At times it would rupture into the bladder, a cystitis would occur temporarily and there would be freedom from pain. The stools would be normal and regular following these attacks for many months. A perforation may occur into an adherent loop of bowel, usually the ileum. If this is permanent, it often causes considerable distress and loss of weight, and in such instances the involved loops may have to be resected. An external fistula may occur either through the abdominal wall where the abscess has been drained, or about the pelvic floor where the abscess has found its way along the muscle and fascial planes. I have not made a practice of closing these. If the diverticulitis should permanently subside, they will automatically close themselves. Otherwise, they should be left as a safety valve for drainage during the attack of diverticulitis.

5. *Diverticula and diverticulitis as a cause of cancer.*

There has been much discussion for many years relative to the relationship of carcinoma to this condition. Shallow, Brown and Marcley have been unable to establish any relationship and conclude that it was largely a matter of chance. It is not uncommon to find carcinoma in patients who also have diverticula, but it has often been noted that they occur frequently in a part of the colon not involved with diverticula. It must be remembered that the common site for both lesions is the sigmoid colon, and that they both occur most frequently in the fifth and sixth decades of life. I have been unable to find anyone who has definitely established a relationship between carcinoma and diverticula of the colon. I, therefore, believe that it can be dismissed as of minor importance.

SURGERY IN DIABETIC GANGRENE

James M. Hayes, M.D.

Minneapolis

Both conservative and radical surgery in diabetic gangrene have been rather widely discussed recently. No surgeon desires to amputate a leg that may be saved and rendered useful.

It is generally agreed that the degree of interference with circulation and infection are the two most important factors influencing the course and treatment in diabetic gangrene.

Surprising as it may seem, there are some reputable surgeons who advise against the amputation of a toe, but favor amputation of the leg in diabetic gangrene of a toe. They maintain that the chances of spreading infection in amputation of a toe is too great to warrant this procedure. Others advise against amputation of a leg in any case because of the high mortality in these cases.

At the Western Surgical meeting last year, I was surprised to hear so good a man as Dr. Maes[2] say nothing short of leg amputation should be done in case of moist gangrene of a single digit.

The introduction of insulin has been a great boon not only to the ordinary diabetic patient but to much greater extent to the one with diabetic gangrene. As in other operations on diabetic patients the blood sugar must first be controlled.

Recently some interesting and exhaustive studies have been made in various clinics over the country on the subject of diabetic gangrene.

One of the most interesting is that by Pearse and Ziegler,[3] of the University of Rochester, New York, which appeared in *Surgery*, July 1940. They reviewed their study of 211 diabetic patients with varying degrees of gangrene of the feet. Their conclusions from this study were as follows:

1. Treat conservatively so long as the lesion or infection is confined to the digit. Twenty-five per cent were cured when treated in this manner.

2. Treat conservatively in case of adequate circulation. Leg amputation is a useless sacrifice in these cases. Ninety per cent of these patients were cured by operation on the foot. Failure of the first operation does not increase mortality nor reduce the chances of success.

3. Conservative treatment is not indicated in the presence of inadequate circulation. Delay in these cases may permit extension of infection in the foot.

4. Removal of gangrenous or infected parts offers no increased risk but the wounds rarely heal.

5. In severe cases, removal of the foot and later leg amputation is indicated.

6. Mortality in acutely infected cases is 45 per cent.

They have attempted to classify these patients as to the degree of interference of circulation.

1. Patients with poor circulation have a history of claudication and rest pain. The member is cold, discolored and pulseless. Trophic changes are present in the skin and nails. There is an absence of popliteal pulse. Calcified vessels are evident and there is no rise of temperature by vasomotor test.

2. Patients with fair circulation have some history of claudication but no rest pain. Pulsations in the dorsalis pedis and posterior tibial are gone but not in the popliteal artery. There is a moderate rise of temperature.

3. In patients with good circulation, slight general symptoms, some pulsation in dorsalis pedis and posterior tibial, toe amputation gave 11 per cent mortality; leg amputation gave 32 per cent mortality. Secondary operations did not increase the rate of mortality. Suppuration in the plantar surface of the foot was a real hazard and usually local operation was avoided.

Leland and McKittrick, in Massachusetts General Hospital, reviewed 559 patients with varying degrees of diabetic gangrene. They advise leg amputation if one or more toes are involved, with involvement of deeper structures and no pulsation in the dorsalis pedis artery; also, if there is osteomyelitis of a phalanx.

William Crawford White says: "It is our practice to advise amputation in any case of diabetic gangrene where the amputation of more than one toe is to be performed. Simple amputation of a toe is unsuccessful because gangrene and infection spread and necessitate leg amputation."

Such widely diversified opinions from surgeons with so great experience leaves the average individual at sea as to how to treat these cases.

In these discussions it would appear that one could draw a definite line between those who could be operated upon locally and those in whom leg amputation is definitely indicated.

I am convinced that the absence of pulsation in the dorsalis pedis, posterior tibial, or even the popliteal artery does not always indicate leg amputation. If these vessels are shut off gradually, the collateral circulation is frequently quite well established. Only by close observation for some period of time can it be definitely determined how much circulation is shut off. Control the diabetic condition and infection, and one can safely wait for developments.

All gangrenous or necrotic areas should be considered infected from the start. To stop the spread of this infection at this point is perhaps the most important factor in the entire process. The large antiseptic wet pack, properly applied for forty-eight hours, gives most satisfactory results in controlling

this infection. One can then wait for the line of demarcation. As soon as this line forms, the necrotic tissue should be cut away. No bone should be left protruding or even near the surface. The wound should not be tightly closed, nor should any tension

Fig. 1. Illustration showing all but great toe missing (Case 5).

be placed on these tissues. The wet antiseptic pack should be applied again after surgical interference.

If the infection has not extended too widely before this pack is applied, it usually is quite readily controlled.

If the gangrenous area extends, repeated operations may be necessary and successful. If the function of the foot is destroyed, then amputation of the foot may be justified, with later amputation of the leg either below or above the knee.

Amputation through the thigh usually occasions considerable shock. Much of the shock may be prevented by the administration of spinal anesthesia.

I have six cases to present in all of which leg amputation had been advised. Four of these six patients are alive and well today, with good functioning feet and legs. Two of them were not seen early, and neither the diabetic condition nor gangrenous areas had been treated in time to save their lives. They are examples of neglect in controlling both the diabetic condition and local infection.

Case 1.—A woman, sixty-eight years of age, had had diabetes for twenty years. She had recently lost her husband and lived alone. She became careless in her control of her diabetes. When gangrene and infection appeared she neglected to consult a physician until her general condition was very poor.

The usual procedure was carried out to save the foot, but the gangrene gradually spread. The leg was amputated in the lower thigh, under spinal anesthesia, but the patient gradually succumbed.

Case 2.—A man, seventy-eight years of age, who lived in the country, had had diabetes for several years and an extensive arteriosclerosis. The gangrene and infection began in the great toe. This extended for some time before any treatment was instituted.

After preliminary treatment, the great toe was amputated. Later, the next toe was cut away. The entire foot then became gangrenous. While we were

Fig. 2. Three toes, the middle metatarsal and most of the first metatarsal have been removed (Case 6).

waiting for the family to consent to amputation, the patient had a cerebral accident and passed out.

With these two patients, the cause of death was perhaps neglect of control of the diabetes and infection in the early stages.

Case 3.—A woman, aged sixty-three, had diabetes for several years. On entering the hospital, she had a 4+ sugar in the urine, and a blood pressure of 210/110. The little toe of the right foot was gangrenous. The antiseptic wet pack was put on for forty-eight hours, and the little toe amputated in December 1930. In March 1931, the third toe of the right foot was amputated; in July 1931, the fourth toe and in December 1931, the second toe of the same foot was amputated. About two years later, the second toe of the left foot was amputated.

At the time of the first amputation no pulsation could be felt in either the dorsalis pedis or the posterior tibial arteries. Today, the patient walks well on both feet with no apparent limp. She has just recently been operated for cataract.

Case 4.—A man, aged sixty-one, had only recently discovered that he had diabetes. His blood pressure was 200/90. There was sugar in the urine. The hemoglobin was 50 per cent, and the leukocyte count was 11,400.

On November 6, 1935, he came to the hospital with an extensive gangrene of the right great toe and surrounding tissues. He came in for leg amputation. After treating the infection, the right great toe and surrounding tissues were cut away. On December 15, 1936, the left great toe was cut away. On January 14, 1937, the head of the left metatarsal was removed and on June 8, 1939, the fourth toe of the right foot had to be amputated. Today, the patient is walking around on both feet in comparative comfort.

Case 5.—A man, aged seventy-six, had diabetes for five years. He had sugar and casts in the urine. His temperature was 100°, and blood pressure 160/70. He had had a cerebral hemorrhage one year previously. He had some paralysis of his right hand and foot at this time.

In March 1939, the left little toe was entirely gangrenous. This was removed. Later three successive operations were done until only the great toe remained. Much of the metatarsal area was also cut away (Fig. 1). Since the right foot is partially paralyzed, this foot is much more useful now.

Case 6.—A man, sixty-five years of age, had had diabetes for several years, and had had a severe endocarditis for some time. The third toe on the right foot had sloughed (Fig. 2).

The metatarsal bone of this toe was necrotic and extensively infected. The great toe and head of the metatarsal bone were gangrenous. The leukocyte count was 10,000; hemoglobin 50 per cent; temperature 99.8°; blood pressure 146/85. The patient came in for leg amputation.

The antiseptic wet pack was put on for forty-eight hours, and all necrotic tissue cut away. The wound was watched closely and healed well after six or seven weeks, with the exception of a slight area over the metatarsal bone of the great toe. On May 16, 1940, the wound was opened and most of the metatarsal bone cut away. The wound is now healed and a good functioning foot remains.

I am convinced that many legs are amputated that could be saved and made useful.

The control of diabetes is comparatively simple since the introduction of insulin. Many operative failures are due to uncontrolled infection. My own experience and that of those who have learned to use the large antiseptic wet pack properly, leads me to believe that this is the most efficacious means of controlling the infection.

Discussion

Dr. John R. Paine: Seven or eight patients at the University Hospital have been injected in the manner indicated since the first of the year by Dr. R. Knight. These patients have been treated by Dr. William T. Peyton and myself as well as by Dr. Knight. I can only emphasize the striking benefits which Dr. Knight has mentioned which occasionally occur in these cases. In quite a number of instances, the pains which these patients complain of have been relieved after injection. Patients with involvement of the arm as well as the leg have been treated, and the results have been the same. The exact indications for the use of such injections, in my opinion, does not appear at the present time to be settled. Further time must elapse and more experience accumulated before anything can be said definitely on this point. We do know, however, that this is the most effective method of treatment we have for a patient with acute thrombophlebitis.

Dr. Ralph T. Knight presented a series of case reports illustrating the treatment of arterio-thrombosis and thrombophlebitis with lumbar sympathetic block.

BOWEL OBSTRUCTION IN PREGNANCY

Lawrence M. Larson, M.D., Ph.D. (in Surgery)
Minneapolis

At first thought it would seem that the continuity of the intestinal tract would be not infrequently interrupted when the uterus enlarges so tremendously as it does in the later months of pregnancy. The displacement of the bowel as well as of other organs is considerable, but because of the slow gradual process of this displacement and the constant movements of the intestinal tract, many compensatory adjustments are made. It is this factor which makes intestinal obstruction such a rare disease in pregnancy.

In over 66,000 deliveries at the Boston Lying-In Hospital from 1916 to 1938 there were sixty-one acute abdominal conditions requiring operation and only one of these represented a patient with intestinal obstruction, so that one can readily realize the rarity of this disease. The most common emergency of a surgical nature was acute appendicitis; next spontaneous rupture of the uterus; and finally tumors such as ovarian cysts or uterine fibroids. Gall-bladder disease occurred rather frequently but required operation in only three instances.

The diagnosis of bowel obstruction is usually a fairly easy matter. However, when this disease is present in pregnancy many difficulties present themselves which are not easy of solution. Furthermore, it is at this time that it is of greatest importance to make an early diagnosis if one is to obtain bests results in treatment of both the bowel condition and the pregnancy. These difficulties are due to the fact that both conditions present symptoms which may be so similar as to be confusing. In both pregnancy and bowel obstruction the presence of vomiting, abdominal pain and distention are to be expected. Furthermore, the presence of a large uterus prevents satisfactory palpation of the abdomen, which adds to the difficulties.

A very deceptive factor in pregnancy is the upward displacement of the abdominal viscera by the enlarging uterus. It is difficult to realize the tremendous change in position of the bowel which takes place when the entire lower abdomen becomes filled by the uterus. The ileocecal junction is usually pushed upwards close to the level of the gall bladder towards the end of pregnancy, and as one can readily determine, this will cause much confusion in diagnosis when an abdominal emergency occurs. Thinning of the abdominal muscles may be so great that muscle spasm cannot be elicited, and this is just another factor contributing to additional difficulties in making an early diagnosis of any abdominal emergency. Appendicitis, gall-bladder disease, peptic ulcer, right sided pyelitis and pleurisy may be almost undistinguishable as far as location of pain is concerned. At this point it may be well to insert that the location of the pain of appendicitis must be sought for at progressively higher levels as the months of pregnancy go by. Other conditions to be considered in

right sided pain are right salpingitis and tumors of the right adnexae, especially those of ovarian origin.

The symptom of vomiting as a rule is not confusing. Early in pregnancy regurgitation is common but it commonly stops by the end of the third or fourth months and with this type of vomiting the abdomen is usually flat and no areas of tenderness can be made out. If the vomiting continues longer than this, one should suspect an organic cause. Furthermore, if pain is an associated symptom, especially if persistent, the diagnosis should be the same as though pregnancy were not present.

During pregnancy severe acute abdominal pain may arise from diseases associated with the condition. This occurs with the rupture of a tubal gestation or if bleeding takes place within the uterus and the blood is retained there. Agonizing pain, shock, and collapse are a constant accompaniment. Late in pregnancy uterine rupture may be the cause of sudden abdominal pain, shock, and collapse.

Probably one of the most common causes of pain simulating intestinal obstruction results if the pedicle of an ovarian cyst or uterine fibroid becomes twisted. Frequently the symptoms of such an ailment begin as a mild attack of pain but occasionally they may be of a sudden severe character and in this type of case there is no question as to there being an acute abdominal emergency present. The diagnosis is established by palpation of the abdomen and recognition of a tumor separate from the uterus. Torsion of a pedunculated fibroid or even of a fibroid uterus itself is a much rarer condition. Another disease sometimes causing confusion with obstruction of the bowel is an infection in the genito-urinary tract. Just as in a non-pregnant woman it is entirely possible for this condition to closely simulate appendicitis. As we all know many appendices have been removed for this reason. The onset, however, is usually associated with a sudden rise of temperature, chills, tenderness and rigidity over the right lower abdomen and abdominal distention. This condition is most common on the right side and is somewhat rare on the left. The diagnosis rests upon urinary findings.

In general it should be emphasized that the principles of recognizing and handling an acute abdominal emergency during pregnancy are the same whether pregnancy is present or not. Furthermore it should be remembered that a differential diagnosis is not always possible. It is of the highest importance to above all recognize that an acute abdominal emergency exists and to manage the situation accordingly.

Case Report

This patient was first seen in September, 1937. She was twenty-four years of age and had always been healthy except for a previous appendectomy in 1932. When first seen she was beginning her eighth month in her first pregnancy which until that time was normal except for probably a little bit more than the usual amount of gaseous distention. She had had much morning sickness and indigestion the first three months of her pregnancy. However, this had improved greatly after that time and she was fairly well then until the onset of the present illness. For forty-eight hours she had had increasingly severe pain in her right abdomen and had vomited several times. She was prostrated from this intestinal upset. The pain came in cramplike waves and was definitely increasingly severe. She had had no bowel movement for about forty-eight hours although she had passed some gas until the past twenty-four hours. No other symptoms could be elicited. On physical examination she gave the appearance of a rather sick individual. Her face was drawn, she was pale and very weak. The temperature was 99.0°, pulse 108. A general examination was negative except for her abdomen. The uterus reached well above the umbilicus and was apparently normal. The position of the fetus could be determined as that of an occiput left anterior. There was a rather large amount of gaseous distention throughout the right half of the abdomen especially in the upper portion. She was quite tender over the appendectomy scar and upward to the lower rib margin. A diffuse rigidity and spasm was present involving the lower abdominal muscles which was slightly more marked on the right side. Auscultation revealed gurgling sound synchronous with the pain in the right side. Rectal examination was negative. The white blood count was 14,600 with a differential count of 92 per cent polymorphonuclears. The blood urea nitrogen was 34 milligrams per 100 c.c. of blood and the blood chlorides 526 milligrams per 100 c.c. of blood. An x-ray flat plate of the abdomen at this time showed the eight months' fetus but also demonstrated the typical parallel ladder-like arrangement of gas and liquid in the small bowel.

Laparotomy was decided upon and a right rectus incision made. A rather surprising condition presented itself when the ileocecal coil was found high on the right side almost up to the gall-bladder area. Moreover a thick fibrous band was present extending from the previous appendectomy scar up to the cecum and was under such tension that it had kinked the cecum enough to completely obstruct it. The bowel was not devitalized and after severing the band, all tension was removed and the kinked coil resumed its normal continuity. Convalescence was uneventful and five weeks later she gave birth to a normal child. Her labor was normal and no damage resulted to the abdominal incision. Examination six weeks post-partum revealed no hernia or weakness in the incision. The incision healed well enough to withstand the stress of a primiparous labor.

Several factors in this case are worthy of emphasis.

First of all, it is difficult to realize the tremendous displacement of abdominal contents, especially the bowel, occurring with the gradual rapid enlargement of the uterus which eventually fills the entire lower half of the abdominal cavity. This displacement tends to crowd the organs into the upper abdomen and adds to the difficulty in diagnosis, whenever any of them becomes subject to disease. This is an important point to remember when appendicitis is suspected, for one must seek the location of the pain at a higher level as the months of pregnancy go by.

Second, in bowel obstruction it is of greatest importance to make an early diagnosis and to consequently institute early therapy. In this particular case, if gangrene of the bowel had occurred, the consequences may have been very serious.

Third, this case again indicates the fact that operations of necessity can be carried out even in the late months of pregnancy.

Fourth, the principles of diagnosis and treatment of acute abdominal emergencies are the same in the pregnant woman as they are in the non-pregnant.

GROWING IN COMFORT ON S-M-A

S-M-A* provides 20 calories to the ounce, but more important, the nutritional value of S-M-A is that of a complete, well-balanced food, specially prepared to help build strong, healthy babies.

An actual test of S-M-A is the only true proof of its exceptional nutritional qualities. Why not write for samples and full information?

" " "

Normal infants relish S-M-A . . . . digest it easily and thrive on it.

" " "

FOR PREMATURE AND UNDERNOURISHED INFANTS

A Special Product

PROTEIN S-M-A

(Acidulated)

Protein S-M-A (acidulated) is a modified form of S-M-A intended to meet the special nutritional needs of the premature and undernourished infant and for infants requiring a high protein intake.

Protein S-M-A (acidulated) is similar to both casein milk and lactic acid milk, but contains additional nutritional elements lacking in both.

*S-M-A, a trade mark of S.M.A. Corporation, for its brand of food especially prepared for infant feeding—derived from tuberculin-tested cow's milk, the fat of which is replaced by animal and vegetable fats, including biologically tested cod liver oil; with the addition of milk sugar and potassium chloride; altogether forming an antirachitic food. When diluted according to directions, it is essentially similar to human milk in percentages of protein, fat, carbohydrate and ash, in chemical constants of the fat and physical properties.

ACCEPTED AMERICAN MEDICAL ASSN. Council on Foods

Speakers at the twenty-sixth annual meeting of the Iowa Tuberculosis Association held in Des Moines, March 27-28, included Dr. Lewis S. Jordan of Granite Falls, Minnesota, who spoke on "Finding the Source and Breaking the Contact"; and Dr. Charles E. Lyght of Northfield, Minnesota, whose subject was "A Challenge to Iowa Colleges."

* * *

Dr. F. M. Feldman, former health officer of the Minnesota Department of Health district office in Mankato and more recently director of rural health, District 3, of the State Board of Health, with headquarters in Rochester, has been named health officer of the city of Rochester. He succeeds Dr. T. B. Magath who resigned that position.

* * *

In conjunction with the meeting of the American Medical Association in Cleveland next month, alumni of the University of Minnesota Medical School will hold an informal get-together at the Hotel Cleveland, June 4, from 5:30 to 7:30 p. m. Dr. Elizabeth Leggett of Kent, Ohio, is chairman of arrangements for the event.

* * *

John R. Anderson, son of Dr. and Mrs. Edward D. Anderson of Minneapolis, has been awarded a scholarship to the Curtis School of Music in Philadelphia and will go there to study next fall.

A student at the University of Minnesota, Mr. Anderson, baritone, was selected recently to sing with the Minneapolis Symphony orchestra at a concert, April 23.

Among the speakers at the annual assembly of the Nebraska State Medical Association in Lincoln, May 5-8, were Dr. Alexander E. Brown of Rochester, whose subject was "Practical Considerations in Sulfamido Therapy," and Dr. Albert V. Stoesser of Minneapolis who spoke on "Chemotherapy in Pneumonia" and "Preventive Allergy—A New Therapy."

* * *

Medical Reserve Officers whose orders have been revoked include:

Dr. Louis Alfred Benesh, first lieutenant, Minneapolis, who had been ordered to Fort Francis E. Warren, Wyoming.

Dr. Jacob Francis Karn, first lieutenant, Saint Paul, who had been assigned to Fort Knox, Kentucky.

* * *

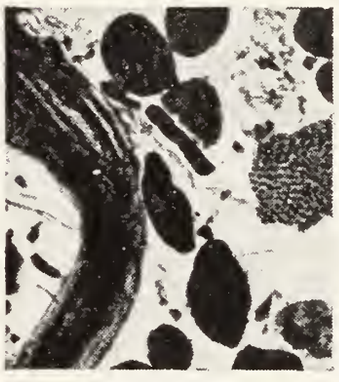
Dr. Earl Cook Elkins of Rochester was in New York last month to address a meeting of the Eastern Section of the American Congress of Physical Therapy. His paper, written in collaboration with Dr. Charles Sheard, was entitled "The Effect of Infra-red Irradiation on Cutaneous Temperatures." While in New York he also attended a meeting of the editorial board of the *Archives of Physical Therapy.*

* * *

Dr. Walter C. Alvarez of Rochester was one of two physicians who presented a course in psychoneuroses in general practice, given April 21, by the committee on postgraduate education of the Medical Society of the District of Columbia, Washington. Dr. Alvarez also spoke at the eighty-fourth annual session of the Missouri State Medical Association held in St. Louis, April 28-30.

* * *

The Minneapolis branch of the Minnesota Society for the Control of Cancer held a luncheon meeting, April 4. Speakers included Dr. F. E. Harrington, health commissioner of Minneapolis; James H. Baker, executive secretary of the Hennepin County Medical Society; Dr. William A. O'Brien, president of the Minnesota Society; Dr. Norman Johnson and Dr. Edgar J. Huenekens of Minneapolis.



* * *

The marriage of Dr. Northrop Beach, medical fellow in pediatrics at University of Minnesota Hospitals, and Miss Caroline Wiggin of Portland, Maine, took place in Minneapolis, February 2. Dr. and Mrs. Beach are making their home at 515 Delaware Avenue, S. E., Minneapolis. Dr. Beach is the grandson of Dr. Cyrus Northrop, one-time president of the University of Minnesota.

* * *

Dr. H. I. Lillie of Rochester and Dr. Frank E. Burch, head of the Department of Ophthalmology and Otolaryngology at the University of Minnesota Medical School, presented several papers at the sixth annual Spring Postgraduate Course, sponsored by the University of Oregon Medical School and the Oregon Academy of Ophthalmology and Otolaryngology, in Portland, Oregon, March 31 to April 5.

STRAINED VEGETABLES
MAGNIFIED 200 TIMES

Note the large bundles of coarse fibers, the many large cells, the closely packed starch granules. Contrast with the photomicrograph at the right, showing Libby's specially homogenized Vegetables. (Process patented U. S. No. 2037029.) Here you see no coarse fiber or large cells; starch particles are small and uniformly distributed.

LIBBY'S HOMOGENIZED VEGETABLES
MAGNIFIED 200 TIMES

As demonstrated in this photomicrograph, special homogenization breaks up cells, fibers and starch particles, and releases nutriment for easier digestion. Libby's Baby Foods—vegetables, fruits, soups, cereal—are first strained, then specially homogenized. This exclusive double process makes them extra smooth, extra fine in texture.

Dr. E. T. Bell, head of the department of pathology at the University of Minnesota Medical School, presented a paper on "The Disuse Atrophy of the Renal Arteries" at the meeting of the American Association of Pathologists in New York City, April 10 and 11.

Dr. Bell also attended the meeting of the American Association for Cancer Research in Chicago, April 15 and 16.

* * *

Dr. William R. Lovelace of Rochester was in Mexico City last month where he addressed, in Spanish, meetings of the Sociedad de Cirujia del Hospital General and of the Academia Nacional de Medicina. His subjects were "Malignant Lesions of the Cecum and Ascending Colon" and "I. Use of Oxygen in Surgery and Medicine; II. Recent Advances in High Altitude Flying."

* * *

When the fiftieth annual meeting of the Arizona State Medical Association was held in Phoenix, April 16-19, the guest speakers included two Rochester men: Dr. Henry F. Helmholz whose subject was "Blood Dyscrasias in Childhood," and Dr. John S. Lundy, "Supportive Measures Including Transfusion of Blood and Plasma, Parenteral Solutions and Stimulants."

* * *

Dr. Wesley W. Spink, assistant professor of medicine at the University of Minnesota Medical School, addressed a meeting of the American Association of Immunologists in Chicago, April 17. The subject of his talk was "The Effect of Ascorbic Acid upon the Bacteriostatic and Bactericidal Action of Human Blood."

On May 5, Dr. Spink addressed the American Society for Clinical Investigation at Atlantic City, New Jersey.

* * *

Applications of 122 students for admission to the freshman class of the University of Minnesota Medical School, for the fall quarter of 1941, have been accepted, according to Dr. C. D. Creevy, assistant dean of the Medical School. This is seven more than were accepted last year.

The committee on admissions is now entertaining applications for the fall quarter of 1942.

Enrollment in the Medical School is now approximately 550, including interns.

* * *

Dr. R. J. Wilkowske, practicing physician and surgeon in Owatonna since September 1, 1939, announces the opening of his own office at 120 West Bridge Street in Owatonna for the practice of medicine and surgery.

Before coming to Owatonna nineteen months ago, Dr. Wilkowske practiced in Nerstrand, Minnesota, for several years. He is a member of the staff of the Owatonna City Hospital and the St. Lucas Hospital in Faribault.

In the little more than four years that medical, hospital and public health continuation study courses have been offered at the University of Minnesota Center for Continuation Study, a total of eighty courses have been offered. These covered a period of 399 days. The faculty for the eighty courses included 1,837 persons, while attendance totaled 3,081. Fifty-nine of these courses were medical; nineteen were concerned with hospitals; and two, with public health.

* * *

Dr. Irvine McQuarrie, head of the department of pediatrics at the University of Minnesota Medical School, addressed a meeting of the Linn County Medical Society in Cedar Rapids, Iowa, April 10. His paper was entitled, "The 'Experiments of Nature' in Clinical Medicine."

On April 8, Dr. McQuarrie discussed his recent visit to China from a nutritional viewpoint, before a meeting of the Minnesota Industrial Chemists Forum in Minneapolis.

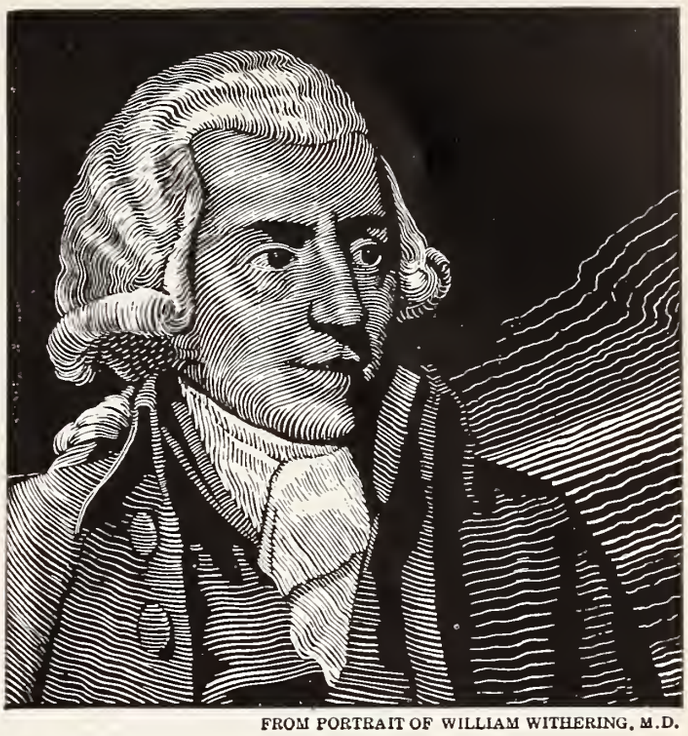
* * *

Dr. Ruth E. Boynton, director of the Student Health Service at the University of Minnesota and president of the American Student Health Service Association, was in New Orleans April 11 to address a meeting of the National Student Health Association, which is composed of student health service staff members in negro colleges. She spoke on the subject, "Educational Opportunities and Responsibilities of the Health Service."

On April 4, Dr. Boynton addressed the Ohio Student Health Association in Columbus, Ohio, on "Responsibilities of the Health Service for Student Housing."

* * *

The annual University of Minnesota Medical School banquet, sponsored by Incus, honorary medical society, was held April 23 at the Coffman Memorial Union. Dr. J. L. McKelvey, head of the department of obstetrics and gynecology, was toastmaster.



Speakers included Dr. E. T. Bell, professor and head of the department of pathology; Dr. B. C. Schiele, assistant professor of nervous and mental diseases; Dr. Moses Barron, professor of medicine; Dr. C. E. Rea, clinical assistant professor of surgery; and Dr. E. S. Platou, clinical associate professor of pediatrics.

* * *

A new course in sight conservation, planned especially for public health nurses but also open to medical school students, will be offered during the first summer session at the University of Minnesota this year.

It is being sponsored by the Minnesota Society for the Prevention of Blindness, the Minnesota Academy of Ophthalmology and Otolaryngology and the National Society for Prevention of Blindness.

The work will be offered under the direction of the University Department of Preventive Medicine and Public Health, headed by Dr. Gaylord D. Anderson. Miss Eleanor W. Mumford, representing the National Society for the Prevention of Blindness, will conduct the course.

WITHERING HEIGHTS

DIGIFOLINE, *"Ciba"* offers the physician a digitalis that may be said to reach the heights of Withering's therapy.

DIGIFOLINE *"Ciba"*

While disputes have raged as to the best method of standardization, Digifoline has not changed in rigidity of potency testing for many years. The physician can always be sure of this:—one tablet, one cc. of liquid, or one (2 cc.) ampule of Digifoline* is equivalent to one cat unit. To sum up: this digitalis preparation is uniform and Ciba is constantly on guard to maintain this high standard. No glycerine or alcohol is present in the ampules, thus eliminating any irritation produced by these substances.

Oral, intravenous, intramuscular or rectal administration in auricular fibrillation, congestive heart failure, loss of cardiac tone, etc.

ACCEPTED AMERICAN MEDICAL ASSN

*Trade Mark Reg. U. S. Pat. Off. Word "Digifoline" identifies the product as digitalis glucosides of Ciba's manufacture.

A series of radio programs has been presented by the Minnesota Hospital Association during April and May. These broadcasts, scheduled from April 14 through May 12, were concerned with various phases of hospital life and administration, such as: executive housekeeping, occupational therapy, hospital auxiliaries, medical and institutional library service, medical and social service, nervous and mental cases, x-ray and laboratory departments, development of the modern operating room, tuberculosis hospitals, medical records, nursing as a career. Dr. W. A. O'Brien was chairman of a round-table discussion on "The Part the Hospital Plays in the Community," April 25; and of another broadcast, over the North Central Broadcasting system, May 11.

* * *

In recognition of his receiving the John Scott Award of the city of Philadelphia and for other honors conferred upon him in the past, Dr. Owen H. Wangensteen, head of the department of surgery at the University of Minnesota Medical School, was honored by his fellows and former fellows at a party at the Minneapolis Club, April 2.

Thirty-five persons were present including Dr. Charles Mead of Duluth, Dr. James Hibbard of Wichita, Kansas, Dr. Leslie Tasche of Sheboygan, Wisconsin, and Dr. Ray Buirge of New Hampton, Iowa.

Dr. George Eitel was toastmaster, Dr. O. J. Campbell presented Dr. Wangensteen with a scroll signed by all the fellows, and each fellow related one outstanding experience while on service. There were many telegrams from persons unable to be present.

* * *

The Women's Field Army, affiliated with the Minnesota Society for the Control of Cancer, conducted a membership drive last month. Mrs. Harlow Hanson of Minneapolis is commander of the field army, and directed the drive. Funds will be used entirely for educational purposes.

Several physicians recently addressed meetings under the auspices of the Women's Field Army. Among those giving these talks on cancer were: Dr. James Dunn of Saint Paul who addressed the Vocational Hospital Alumnæ in Minneapolis, March 19; Dr. Charles Craft of the University of Minnesota Hospitals, who spoke before the Hector, Minnesota, High School and the Women's Club, March 25; and Dr. William A. O'Brien, president of the Minnesota Society for the Control of Cancer, who addressed the Nicollet-LeSueur County Medical Auxiliary at St. Peter, April 15.

* * *

To avert a possible national shortage of doctors, the Selective Service System has ordered deferment of military training for medical students who "give reasonable promise of becoming acceptable medical doctors."

A memorandum from Brigadier General Lewis B. Hershey, selected service deputy director, instructs state and local boards to continue such deferments as long

as the students progress satisfactorily. Local boards are also urged to make sure that requirements of the armed forces for physicians and surgeons are filled, without summoning to military duty practicing doctors whose services are necessary to the community.

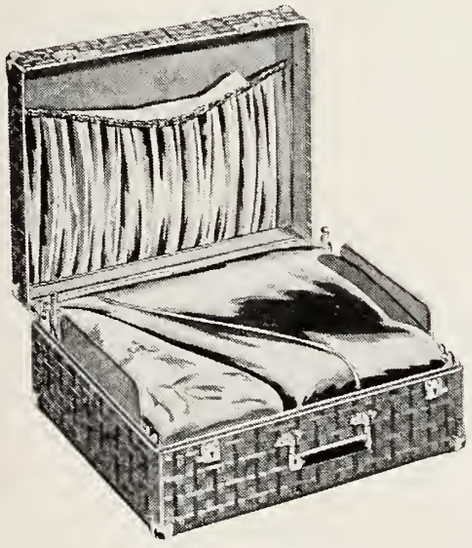
It is estimated that there is a need for 9,000 medical officers for the Army, Navy, Public Health Service and Veterans Administration. To fill that need would remove about 5 per cent of the doctors now engaged in civilian practice.

* * *

Medical Reserve officers ordered to extended active duty within the past few weeks include:

Dr. Leonard K. Buzzelle, first lieutenant, Minneapolis, assigned to Camp Joseph T. Robinson, Arkansas.
Dr. Malcolm R. Johnson, captain, Red Wing, to Fort Riley, Kansas.
Dr. Edward John Low, first lieutenant, Mahnomen, to Fort Sam Houston, Texas.
Dr. Kenneth Eben Bray, first lieutenant, Park Rapids, to Fort Knox, Kentucky.
Dr. Nesmith Perry Nelson, captain, Brainerd, to Fort Knox.
Dr. Arthur Neumaier, first lieutenant, Lindstrom, to Fort Knox.
Dr. William Martin O'Brien, captain, Saint Paul to Fort Knox.
Dr. Everett Charles Perlman, captain, Minneapolis, to Fort Knox.
Dr. Harry Louis Plotke, first lieutenant, Little Falls, to Fort Meade, South Dakota.
Dr. Carl Walter Rumpf, captain, Faribault, to Fort Knox.
Dr. Paul A Swedenburg, captain, Swanville, to Fort Knox.
Dr. Floyd Ammann Thompson, captain, Saint Paul, to Fort Knox.
Dr. Robert Johnson Cairns, first lieutenant, Sanborn, to Camp Joseph T. Robinson, Arkansas.
Dr. George John Halladay, first lieutenant, Brainerd, to Camp Joseph T. Robinson.
Dr. James Frederick Shandorf, first lieutenant, Northfield, to Camp Joseph T. Robinson.
Dr. Edwin Gerhardt Trytten, first lieutenant, Middle River, to Camp Joseph T. Robinson.
Dr. Clifford Orvis Erickson, first lieutenant, Rochester, to induction station, Fort Snelling, Minnesota.
Dr. Raymond Paul Hawkinson, captain, Robbinsdale, to induction station, Fort Leavenworth, Kansas.

* * *



Dr. William Richardson Bagley, pioneer Duluth physician, has been selected as the seventeenth member of the Duluth Hall of Fame. Announcement of his selection as Duluth's "First Citizen" for 1940 was made at the seventeenth annual Hall of Fame dinner, March 29. The gathering, attended by 800 persons, including prominent Minnesota and Wisconsin state officers and leading Legionnaires, was addressed by Milo J. Warner, national commander of the American Legion.

In making the award, Dr. Bagley's work last year in the Duluth, state and national Izaak Walton leagues, his service as a member of the board of directors of the Chamber of Commerce, and his community leadership as president of the Rotary club, were cited. Recognition was also given Dr. Bagley for his active participation in the civic life of Duluth during his long period of residence in Duluth and for his forty years of medical practice.

Forrest C. Huyck, chairman of the Hall of Fame committee of Wisted Legion post, presented Dr. Bagley with the Legion plaque, emblematic of his membership in this "immortal body." Later Dr. Bagley's picture will be hung in the Hall of Fame corridor in the City Hall.

U. S. GENERAL HOSPITAL UNIT NO. 26

Dr. L. Haynes Fowler of Minneapolis has been named unit director of the United States General Hospital Unit No. 26 at the University of Minnesota, an inactive unit which will mobilize and become available for any theater of operation in event of a national emergency.

One of several such units organized in the United States in the interest of national preparedness, this hospital unit has been formed under the direction of Dr. H. S. Diehl, Dean of Medical Sciences. Requisite for membership is affiliation with the University of Minnesota and acceptance in the Medical Reserve Corps of the United States Army after recommendation by the organizing committee. Any medical men desiring affiliation with the unit should make application to Dr. Diehl or the unit director, Dr. Fowler.

Heading the various services are: Dr. Joseph Borg, medical service; Dr. Fowler, surgical service; Dr. Gerald T. Evans, laboratory service; Dr. Earl W. Nelson, dental; and Dr. Oscar Lipschultz, x-ray service. Major Robert N. Barr is detachment commander.

The complete personnel of the unit, as it is now constituted, follows:

Administrative Personnel

Detachment Commander: Major Robert N. Barr
Mess Officer: Major Reuben Erickson
Receiving Officer: Gordon C. MacRae
Captains: Richard H. Barnes, Lyle J. Hay, Robert C. Schenk
First Lieutenant: Lyle French
Second Lieutenants: Norman O. Holte and Dale D. Shepard

Medical Service

Chief of Service: Lt. Colonel Joseph Borg
Assistant Chief of Service: Major Royal C. Gray
Majors: A. B. Baker, Douglas Head, Philip Hallock, and Sam Weisman
Captains: T. J. Bulinski, Robert K. Grau, W. H. Hollinshead, Robert Johnson, Russell C. Lindgren, Stanley W. Lundblad, Robert Meller, Lawrence M. Nelson, Charles Polan, and Karl d'Andresen.
First Lieutenants: David Craig, D. W. Hilger, LaVern C. Strough, Rodney F. Sturley, Evrel Larson, and John Haserick.

Surgical Service

Chief of Service: Lt. Colonel L. Haynes Fowler, and Unit Director.
Assistant Chief of Service: Major John R. Paine
Majors: Edward T. Evans, Charles E. Rea, Jerome A. Hilger, Logan Leven, and Wallace Ritchie.
Captains: George Bergh, Kenneth E. Fritzell, Meyer Z. Goldner, Baxter Smith, Louis Sperling, Karl E. Sandt, Theodore L. Stebbins, Leonard Titrud, and Conrad Holmberg.
First Lieutenants: Carroll Bellis, Harry Hall, and Herman Koschnitzke.

Laboratory Service

Chief of Service: Major Gerald T. Evans
Captain: Robert Hoebbels
First Lieutenant: Milton Levine

Dental Service

Chief of Service: Major Earle W. Nelson
Captain: Harold G. Worman
First Lieutenants: Lyle A. Brecht, Anthony J. Scholtis, and John F. Tenney.

X-ray Service

Chief of Service: Oscar Lipschultz
Captain: Jack Chalek

In Memoriam

Russell Stewart Bacon

Dr. R. S. Bacon, a resident of Montevideo, Minnesota, for over fifty years, died March 29, 1941 at the age of eighty-one.

Dr. Bacon was born May 28, 1859 at Elroy, Wisconsin. His mother died when he was four years of age and when he was eight he lost his father. From that time on he made his own way with the help of friends of the family.

He graduated from the Mauston, Wisconsin high school in 1880 and received his medical degree from Rush Medical College, Chicago, in 1885. He worked his way through medical school teaching and working on a street car line in Chicago. Postgraduate work was taken later at New York University and Tulane University.

In 1886 Dr. Bacon settled at Dawson. He was located at Appleton from 1887 to 1889 when he moved to Montevideo.

Dr. Bacon was active in the early development of his community. He had been an active Mason since 1889 and a Knights Templar since 1890. He had long been a member of the Camp Release District Medical Society, the Minnesota State and American Medical Associations. He maintained his office until last September.

Dr. Bacon served on the draft board during the World War, was a member of the Montevideo school board from 1909 until 1919, was secretary of the United States Pension Board from 1890 until 1929 and was on the Board of Directors of the Riverside Sanatorium from 1917 to 1937. Though an Episcopalian he attended the Congregational Church of Montevideo.

In 1893 Dr. Bacon married Alice Gallinger at Cottage Grove. Two sons, Arthur R. Bacon of Montevideo, and Guy S. Bacon of Cottonwood, survive.

Joseph Franklin Bond

Dr. J. F. Bond, Wabasha, Minnesota, died March 27, 1941, from coronary thrombosis in his eightieth year.

Dr. Bond was born in Versailles, Illinois, July 21, 1861. Graduating from Rush Medical School in 1885 he located in Scott County Kansas. In 1897 he married Harriet Riley and moved to Wabasha where he remained until the time of his death.

At one time Dr. Bond served as city physician and was a member of the library board. He became a member of the Wabasha County Medical Society in 1901 and served as president in 1902-1903. In recent years he was an honorary member of the society.

Dr. Bond was ever alert to the best interests of his profession and in the early days did much for Saint Elizabeth's Hospital in the formative period of that institution.

Mrs. Bond died in Wabasha in 1933. A sister, Mrs. J. Gaut of Versailles, Illinois, survives.

GOOD EATING in our 3 restaurants: Mezzanine Tea Room, Mezzanine Sandwich Shop and the Coffee Shop in the Downstairs Store.

IN MEMORIAM

(Continued from Page 407)

Griffith Moses Jones

Dr. G. M. Jones, Minneapolis, died April 16, 1941 at the home of his daughter, Mrs. T. C. Morris, at Petersburg, Virginia.

Dr. Jones was born in Wales, April 25, 1870 and came to this country as a young man. He received his preliminary education at Redfeld College in South Dakota and at Ripon College in Wisconsin. He received his M.D. at the University of Illinois College of Medicine in 1905 and interned at Saint Joseph's Hospital in Saint Paul.

Dr. Jones practiced in Cambria, Wisconsin from 1905 until 1909. He took postgraduate work at Long Island College Hospital, New York, and at the Children's Memorial Hospital in Chicago, and specialized in pediatrics.

Dr. Jones was an Elder in the Welch Presbyterian Church of Minneapolis. He was a member of the Masonic Lodge and of the Hennepin County Medical Society, the Minnesota State and American Medical Associations.

John Knotz

Dr. John Knotz, Cologne, Minnesota, died on March 3, 1941, at the age of sixty-eight.

Dr. Knotz was born in Austria, September 10, 1872. When ten years old he came with his family to Minneapolis. He received his early education in Saint Joseph's School in Minneapolis and graduated from the medical department of Hamline University in 1897.

Dr. Knotz was married to Rosa Partoll on August 16, 1897 in Minneapolis. After a short time spent in South Dakota he moved to Cologne where he carried on an extensive practice for forty-three years.

Communication

Tricks and Devices of Narcotic Drug Addicts

At the request of Dr. L. L. Sogge, chairman of the Committee on Public Policy, Minnesota State Medical Association, the following information concerning tricks and devices of narcotic drug addicts has been submitted for publication by Harry D. Smith, District Supervisor of the Bureau of Narcotics.

The last eighteen months of changing world conditions has had a marked effect on the narcotic situation, as a result of which illicit supplies have practically disappeared in some localities and become increasingly scarcer in others. There has been a tremendous increase in the efforts made by addicts to obtain narcotics by illegal means from legitimate sources, these efforts ranging from the burglary of wholesale and retail drug stores to ordinary thefts, fraud and deceit, forgery of prescriptions and well simulated symptoms of physical suffering incident to various ailments.

In numerous instances a single individual of either sex has used many aliases and obtained prescriptions from separate physicians within a comparatively short period, and particularly is this true in the rural districts where several physicians in different towns have been visited by such persons using different names (aliases) the same day, and by this means succeeded

in accumulating sufficient morphine for their own comfort and a supply for resale.

Discussions with many physicians have disclosed that while they were acting in good faith, they had in many instances furnished prescriptions or dispensed narcotics practically upon request, often without any medical examination and even without seeing the patient.

The situation from the addiction standpoint is really serious, while the necessity for the conservation of narcotics is of the utmost importance, and I am outlining a number of points in relation to which your coöperation and that of the members of the medical profession would be most useful.

Complaints are frequently heard from pharmacists that many physicians insist upon "telephoning in" their narcotic prescriptions to drug stores and want them filled before the written order is in the druggist's hands. If the druggist fills such a telephonic order, he commits an offense under the Federal Narcotic Law.

Equally specific complaints have been made that certain physicians, upon being informed by the druggist that telephoned prescriptions could not legally be filled, have not hesitated to threaten such druggists that they would send their business elsewhere if their telephoned prescriptions were refused. I am sure that the physician would not desire to place the druggist in the position of violating the law and that this reference to the matter will tend to end such practices.

The following points are suggested as worthy of consideration by the members of your profession in connection with efforts to conserve the narcotics in the United States by restricting their use to legitimate medical purposes only.

1. Always sign and date a prescription for narcotics or preparations containing same, and do not ask the druggist to fill it until he has received and examined it. The druggist has no option, and any variation may result in trouble.

2. Do not issue narcotic prescriptions without making an examination sufficient to satisfy yourself that the narcotic is necessary for purposes other than to satisfy addiction.

3. Narcotic prescriptions should not be issued to a third party who endeavors to obtain one for a "patient" unknown and whose symptoms are described but who is not present.

4. Look with particular suspicion upon requests for prescriptions consisting of Laudanum and Olive Oil. Many of these have been issued to addicts who invariably separate the opiate from the oil and use the former hypodermically.

5. Be extremely cautious in furnishing narcotic drugs to any person on representation that he is in a traveling status enroute to some distant institution for treatment of narcotic addiction. Carefully safeguard against being deceived by transient addicts simulating pain ordinarily recognized incident to acute attacks of certain chronic conditions, and particularly is this suggestion advisable where the unknown individual suggests a narcotic as the only relief possible.

6. Be on the alert against the addict who attempts to secure a narcotic by promises to submit to hospitalization at a later date.

The tricks of addicts are so many that it would be difficult to enumerate them herein, and with the thought in mind that this circular is informative only, I trust that the mutual efforts of the doctor, druggist, and this Bureau may keep at a minimum the amount of drugs available to the illicit narcotic traffic.

MEDICAL BROADCAST FOR MAY

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Professor of Preventive Medicine and Public Health, Medical School, University of Minnesota.

May 3—Summer Round-up
May 10—The Community Hospital
May 17—Maternal Hygiene
May 24—Better Health for Babies

COURSE IN ROENTGEN DIAGNOSIS OF NON-TUBERCULOUS DISEASES OF THE LUNGS AND PLEURA

A study course in Roentgen Diagnosis of Non-tuberculous Diseases of the Lungs and Pleura will be offered at the University of Minnesota Center for Continuation Study, May 22, 23 and 24, it is announced by Dr. William A. O'Brien, director of postgraduate medical education. Enrollment is limited to physicians with special training in radiology.

MINNESOTA PATHOLOGICAL SOCIETY

Dr. Irvine McQuarrie, head of the pediatrics department at the University of Minnesota, will give The President's Address at the meeting of The Minnesota Pathological Society, May 13. His subject will be "The 'Experiments of Nature' and Clinical Investigation."

UNIVERSITY MEDICAL ALUMNI ASSOCIATION

The annual banquet of the University of Minnesota Medical Alumni Association, which will be a feature of the Minnesota State Medical Association meeting next month, will be in the form of a buffet supper to be held at the Casino in the Saint Paul Hotel, Monday, May 26, at 6 p. m.

Following the supper, Clifton M. Utley, director of the Chicago Council on Foreign Relations, will address the group on "America in a World at War." Mr. Utley, an authority on foreign affairs, has participated many times in the University of Chicago round-table discussions which are a Sunday evening radio feature.

All physicians attending the state meeting are invited to the supper, arrangements for which are being

AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

The annual meeting of the American Association for the Study of Goiter will be held at the Hotel Statler in Boston, Massachusetts, May 12, 13 and 14.

The program for the three-day meeting will consist of papers dealing with goiter and other diseases of the thyroid gland, dry clinics and demonstrations.

MINNESOTA HOSPITAL ASSOCIATION

The state convention of the Minnesota Hospital Association will be held May 22, 23 and 24 at the Hotel Lowry in Saint Paul.

The first general session will be called to order at 2 p. m., May 22. Speaker at the supper that evening will be J. H. Norby of the Columbia Hospital in Milwaukee.

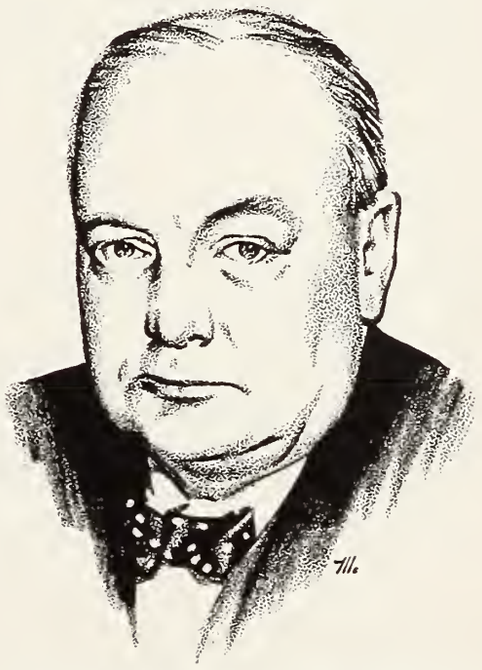
Highlights of the program May 23 will be a round table discussion in the afternoon led by James J. Drummond of Rochester, and the convention banquet.

Saturday, May 21, Dr. A. C. Bachmeyer of the University Clinics, University of Chicago; Ada Belle McCleery of Evanston, a trustee of the American Hospital Association; and Dr. M. T. MacEachern of the American College of Surgeons, Chicago, will address the final general session. Paul Fesler, who has made a survey of hospital facilities in Minnesota, will present a report on "Minnesota Hospitals in National Defense."

At this convention, Ray Amberg of the University of Minnesota Hospitals retires from the presidency, and Miss Esther Wolfe, president-elect, succeeds him.

SCOTT-CARVER MEDICAL SOCIETY

Dr. Henry Ulrich of Minneapolis presented several cases of "Retroperitoneal Tumors" and Dr. Thomas Lowry, also of Minneapolis, talked on "Lung Abscess," at the regular monthly meeting of the Scott-Carver County Medical Society, April 8, at the new Nagel Hospital in Waconia. Opened last October, the Nagel Hospital has a capacity of twenty beds and four bassinets. The one-and-a-half-story building is fireproof and has all modern equipment including x-ray deep therapy. It has its own emergency line power plant. Dr. H. D. Nagel of Waconia is chief of staff.



WASHINGTON COUNTY MEDICAL SOCIETY

At the regular monthly meeting of the Washington County Medical Society, held April 8, at the Stillwater club rooms, Dr. Frank Adair of Saint Paul was the guest speaker. His subject was "Manifestations of Vitamin B Complex Deficiencies."

A bill, Senate File 1034, for regulating ambulance service was brought before the meeting, and the

Britain's Man of the Hour Says—

"If I Had My Way . .

. . . . I would write the word 'INSURANCE' over the door of every cottage and upon the blotting book of every public man, because I am convinced that for sacrifices which are inconceivably small, families can be secured against catastrophes which would otherwise smash them forever."

county society's legislative committee strongly recommended its passage.

Visitors at the meeting included Dr. Carl L. Larsen of Saint Paul; Dr. Frank Giles and Dr. H. Kennelly, medical officer at the Bayport CCC Camp.

OBSTETRIC COURSES

The Illinois State Department of Public Health and the Children's Bureau, U. S. Department of Labor, are sponsoring ten 4-week courses in obstetrics at the Chicago Lying-in Hospital during the fiscal year 1941-1942. Only a limited number of physicians will be accepted for each course. The only cost to the individual is for room and board and $25.00 ($10.00 of which is refunded at the completion of the course). Applications and inquiries should be addressed to: Postgraduate Course, Department of Obstetrics and Gynecology, 5848 Drexel Avenue, Chicago, Illinois.

WOMAN'S AUXILIARY

MRS. M. A. NICHOLSON, Duluth, Minnesota, *President*
MRS. E. V. GOLTZ, 2259 Summit Avenue, Saint Paul, *Publicity Chairman*

This is the *Last Call* for reservations for the *Nineteenth Annual Convention* of the Woman's Auxiliary of the American Medical Association which will be held at Hotel Carter in Cleveland, June 2-6. All Cleveland extends a hearty welcome to you.

Princeton, Minnesota was the meeting place, March 28, for the members of the *East Central Medical Auxiliary*. An interesting talk was given by Mrs. T. M. Olsen of Elk River, District Commander of the Women's Field Army for the Control of Cancer. The Auxiliary pledged its support in the coming drive. Newly elected officers for the year are: Mrs. A. B. Roehlke, Elk River president; Mrs. Williard Nordman, Mora, vice president; Mrs. L. H. Hedenstrom, Cambridge, secretary and treasurer. Mrs. Gordon H. Tesch, Elk River, was named publicity chairman.

Hennepin County Auxiliary gave its annual post-Easter party Monday, April 14. Mrs. L. R. Boies was chairman with Mrs. R. S. Ylvisaker co-chairman. The following members, representing various districts in the city, acted as chairmen for the various parties: Mrs. C. W. Pollard, Mrs. L. F. Richdorf, Arthur La Pierre, J. G. Davis, C. W. Laymon, J. B. Carey, Rollo Stewart, P. E. Petersen, Reuben Erickson, Milton Seifert, James Blake Jr., Archie Smith, G. M. Koepcke, Joseph Neal, W. K. Haven, A. H. McFarland, L. R. Scherer, J. H. Moe, J. H. Simms, Frank Bryant, Ernest R. Anderson, R. R. Sullivan, J. C. Hultkrans, W. R. Jones, J. K. Moen and L. J. Leonard.

Mower County Auxiliary met March 24 in Austin at the home of Mrs. H. B. Allen. A dessert luncheon was served at one o'clock. Several articles from the *Women's Auxiliary Bulletin* were read by Mrs. Carl Eckhardt. Mrs. C. C. Allen, chairman of the Public Relations Committee, explained the project of a survey of women's health interests to be conducted in this county.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

Books Received for Review

The Mask of Sanity. Hervy Cleckley, B.S., B.A. (Oxon.), M.F. Professor of Neuropsychiatry, University of Georgia School of Medicine, Augusta, Ga. 298 pages. Price, $3.00, cloth. St. Louis: C. V. Mosby Co., 1941.

The Essentials of Applied Medical Laboratory Technic, J. M. Feder, M.D. Director of Laboratories and Allergic Service, Anderson County Hospital, Anderson, S. Car. 241 pages. Illus. Price $5.00, cloth. Charlotte, N. Car.; Charlotte Medical Press, 1940.

Essentials of Dermatology. Norman Tobias, M.D., Senior Instructor in Dermatology, St. Louis University; Assistant Dermatologist, Firmin Desloge and St. Mary's Hospitals; Visiting Dermatologist St. Louis City Sanitarium and Isolation Hospital. 497 pages. Illus. Price, $4.75, cloth. Philadelphia: J. B. Lippincott Co., 1941.

Hemorrhagic Diseases. Photo-Electric Study of Blood Coagulability. Kaare K. Nygaard, M.D. Former Fellow in Surgery, Mayo Foundation; Former Assistant Surgeon, University Clinic, Oslo; Fellow of Alexander Malthe Foundation for research in Medicine, Surgery and Gynecology. 320 pages. A NEW IDEA

for only

$29.95

Here is ideal heat relief at low cost. Kisco CIRCULAIR units employ an entirely new principle of cooling by keeping all the air in a room constantly recirculating. An ordinary fan only pushes a blast of air forward in one direction, but the CIRCULAIR lifts the cooler, low air up from the floor and distributes it in all directions at the same time throughout the room. There are no blasts or drafts to create discomfort, muss hair, or disturb papers and light objects. Be prepared for hot weather; ask our salesman for a demonstration.

Illustrated, the LO-AIR, splendid for home or reception room. Finished in black and chrome.

BROWN & DAY, Inc.

CARDIAC CLASSICS. A Collection of Classic Works on the Heart and Circulation with Comprehensive Biographic Accounts of the Authors. Fifty-two contributions by fifty-one authors. Frederick A. Willius, M.D., M.S. in Med. Chief, Section on Cardiology, Mayo Clinic; Professor of Medicine, Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota; and Thomas E. Keys, A.B., M.A. Reference Librarian, Mayo Clinic; formerly Carnegie Fellow, Graduate Library School, University of Chicago. 858 pages. Illus. Price, $10.00, cloth. St. Louis: C. V. Mosby Co., 1941.

PRECLINICAL MEDICINE; preclinical states and prevention of disease. MALFORD W. THEWLIS, M.D. Baltimore; Williams and Wilkins, 1939. $3.00. 223 pages.

In this concise book the author has succeeded in outlining the more important considerations having to do with a very early approach to disease prevention. A foundation is laid for the study of the very early deviations in the human mechanism which may lead to definite clinical disease at a later period.

The opportunity as well as the responsibility of the family physician in recognizing preclinical leads is emphasized. Such factors as disease soils, conditioning periods, and individual vulnerability, are stressed. The author presents outlines which the interested practitioners may follow in accumulating and evaluating the material he obtains. This material information may be used to arrive at a so-called synthetic diagnosis.

Stress is laid on the fact that the study of preclinical medicine and the prodromal period of actual clinical disease are not the same phases of disease.

There are brief references to the various systems and some discussion is presented of the recognition of preclinical signs in the individual.

The book is compact, clearly written and one should find interest in its content as well as inspiration in the possibilities offered.

L. R. CRITCHFIELD, M.D.

SCIENCE AND SEIZURES—NEW LIGHT ON EPILEPSY AND MIGRAINE. Wm. G. Lennox, M. D., Associate Professor of Neurology, Medical School, Harvard University. 239 pages. $2.00. Harper Brothers, 1941.

It is unusual that an outstanding scientist such as Dr. Lennox produces as readable, understandable, and yet so sound a book as this on so complicated a topic. It has been written for the benefit of the parents or relatives of the convulsive group, but is equally valuable for the orientation of the general physician who does not care to delve too deeply into the more complex aspects of these disorders. The historical background of the fears and superstitions that have long surrounded the dreaded epilepsy are reviewed and dispelled so that

convulsive attacks emerge on a social level of acceptance akin to tuberculosis and cancer.

Dr. Lennox, in his recent research, has brought much additional light on the origin of the convulsive attacks through his studies with the electro-encephalogram. These are carefully described in this work. His section on the importance of psychological factors and their influence on the frequency of the attacks is admirably presented. The discussion of the various types of drug therapy is valuable. His comments on the social, industrial, and hereditary aspects of convulsive attacks and the responsibilities they place on the patient and his family are frank and level-headed.

The second section devoted to a discussion of "headache seizures," or migraine, presents some thought-provoking material that is of great significance.

This book is one that any physician who has in his practice one or more patients with convulsive attacks in families of average intellectual capacity would find most useful in gaining their coöperation and understanding and thereby ease his own responsibility. The royalties from the sale of this book, Dr. Lennox states in his introduction, will be devoted to furthering the much-needed research in the field of convulsive disorders.

GYNECOLOGICAL MALIGNANT DISEASE*
Some Problems in Treatment

J. L. McKELVEY, M.D.
Professor of Obstetrics and Gynecology
University of Minnesota
Minneapolis, Minnesota

THE object of this paper is to discuss some of the problems which are met in the handling of gynecological malignant disease. These are not only problems related to the diagnosis and handling of specific neoplasms but are often problems of a general nature which are shared by those who handle malignant disease elsewhere in the body. It would seem wise to establish before a group such as the members of the Clinical Club at least the development of the attitudes of the gynecological group toward these problems.

Certain facts should be clearly stated at the outset in order that later confusion may be avoided. In the first place, while a few broad general principles are applicable to the tumor problem as a whole, these must always be qualified when applied to specific tumors. It requires no further argument to establish the fact that each tumor type is a distinct entity and that variations in natural history and the diagnostic and therapeutic problems are so great that attempts to apply general principles from one to another are not well based. A clear and precise knowledge of the available information in regard to any individual tumor is a sine qua non for its adequate handling.

The second important point to be made will perhaps strike you as absurd. It may seem strange that accuracy should be demanded in the handling of a disease condition about which so little of a fundamental biological nature is known and where therapeutic failure reaches such magnitude. Very considerable degrees of skill and experience are required for diagnosis and in the carrying out of either radiological or surgical therapy of malignant disease. In all of these fields carelessness or unwarranted pretense of authority leads on to serious disaster from which there is likely to be no returning. It is quite clear that the first attack in the matter of histological diagnosis and surgical or radiological therapy is all important. Chance for subsequent fruitful correction of errors in these fields is almost hopeless. For the most part, the surgical technics in the tumor field are delicate and extensive. The radiological attack involves working in a narrow range beyond which too little or too much are equally disastrous. The results of second attempts with either radiation or operation are too well known to require further discussion. The intelligent individual working in this field will develop a serious sense of humility and an earnest desire for accuracy and constant vigilance. He may perhaps be pardoned for some lack of tolerance for the ill-equipped amateur who goes blithely on his way "where angels fear to tread."

The third point which might be made at the outset has to do with an all too wide acceptance of the principle that control of the tumor patient can be efficiently divided into three separate and distinct divisions. There is no reasonable justification for the radiologist, the clinician and the pathologist each ignoring the others' fields. The ultmate ends of our struggle are the welfare of the patient and the progression of knowledge. Both of these are served by a constant check of one group on the other and the sharing of problems and information. It is one's opinion that efficiency is not complete until each group

*Presented before the Minneapolis Clinical Club, December, 1940.

is able and willing to accurately and critically evaluate the problems of the other two. It might be pointed out that those in the three groups who work with gynecological tumors have rather by accident than by design, progressed further in this direction than those in most but not all other fields. This is probably due to two fortuitous circumstances. The German school has until recently led modern gynecological thought and has bequeathed to us the concept of a histological and physiological base for the specialty. The peculiar features of cervical carcinoma made it attractive as a proving ground for radiation therapy. Radiology and histology early became accepted as half-brothers by gynecology and have by and large magnificently accepted their new tasks and relationships. The three must now understand one another entirely if a stable basis for progress is to be laid. Already a new child of astounding proportions, the radio-physicist, is well on his way toward confounding the family peace. And unless all judgment be false, we might just as well prepare bed space at once for new twins, the tumor physiologist and the tumor biologist. What a stirring family this is likely to be!

The scope of this paper necessitates the choice of only a few problems for discussion and no claim can be made to completeness. The old arguments about the relative value of surgery and radiation as a primary attack upon squamous cell carcinoma of the cervix and the question of the organization of tumor clinics will not be considered.

A problem which will require early consideration is the question of the hospitalization of the patient undergoing radiation therapy in the lower abdomen. One can speak feelingly about this in view of experiencees with both out-patient and in-patient therapy. There is every reason to believe that there is value to be obtained from modern massive radiation therapy. In the author's own short experience the x-ray dosages have been nearly doubled. Where this is applied as in the pelvis with large fields and resultant large volume dosage, a considerable number of serious side effects appear which must be recognized and treated early and efficiently if the patient is to be protected and if the therapy is to be continued so that the biological dosage is not to be spoiled by disturbances in the time factor and relative recovery rates. It has been learned that skin, bladder and gut can be protected by control of the necessary factors and these are scarcely applicable except by institutionalization. Protection from the spread of infection by local procedures and accurate observation of early danger signs can be carried out efficiently only with the patient under complete control. The early recognition of red cell, lymphocyte and granulocyte destruction is of great and occasionally vital importance. Recognition of the necessity for the preservation of normal tissue in a sufficiently healthy state so that it can recover and scar effectively, has not only had an influence on the determination of dosage but has produced an awareness of the necessity of controlling anemias by food and transfusion. These are not out-patient procedures and it is suggested that routine hospitalization is essential to efficiency and massive dosage.

Two questions will immediately arise. Is massive dosage, as it is used at present, justifiable? And is it economically possible to institutionalize all such patients that require this form of therapy?

All the weight of experimental, theoretical and clinical evidence presently available, would seem to entirely support the massive dose technics. Schmitz, of Chicago, who has carried the dosage in pelvic x-ray irradiation well beyond those ordinarily used, has been able to show survival rates which are better than those previously obtained and it may well be that we are headed for still more massive therapy. It should be understood that increase in dosage must be measured, insofar as possible, in terms of biological dosage. Increasing physical units of energy delivered alone, does not constitute increase of biological dosage. At the University of Minnesota Hospital relatively small dosages have been previously applied. The recovery rate in squamous cell carcinoma of the cervix under those conditions has been found to be 20 per cent. If this is an adequate sample, as there is every reason to believe that it is, massive dosage may be expected to increase that by 50 per cent and there is some hope in the survival rates to date that this is being attained.

The economic possibilities bring up questions which are not yet solved. What is perfectly clear is this. If an improvement in recovery rates can be demonstrated for the institutionalized patient, and I believe it can, then some method of institutionalizing them must be found.

It is rather surprising that there is not general agreement on the order in which x-ray and radium should be given in such a lesion as cervical carcinoma. There is a very definite primary mortality associated with radiation in this disease and the great majority of these patients die from infection spread. Occasionally, tuberculosis is present in the pelvis and sudden massive dosage will spread this about in a disastrous fashion. The use of preliminary x-ray in divided doses allows the physician to watch the patient's response and to manipulate the dosage as required to meet disturbances as they become evident. During the four weeks approximately during which x-ray irradiation is given, the infected tumor mass is for the most part sloughed away and clinical experience has taught that it is then safer from the point of view of infection spread to apply intrauterine radium containers. It is also possible that the castrated tumor cells will show to a lesser degree than those which have not been radiated, the undesirable response to trauma which is so well known.

This same question of the effects of trauma upon tumor spread has been raised in considering the desirability of preliminary biopsy. Some authors have reported observations in which biopsy was followed by explosive widespread metastasis. It is clear that this is an occasional occurrence in non-traumatized tumor. Dr. Robert Meyer has studied surgically removed breast cancer which had been biopsied without finding evidence of fresh metastases. The value of biopsy in diagnosis is clear and many serious errors will be avoided by its use. But the experimental evidence in regard to the disturbances brought about by trauma to malignant tumor is also clear. It would seem that biopsy should always be carried out but it should be associated with an absolute minimum of trauma. Some form of cutting current loop recommends itself for this purpose.

The question of the control of dosage and its division, as applied to tumors at depth in the pelvis at least, will not be well based until more is known of the biology of the absorption of radiation energy. It has been gradually established by clinical experiment that the best results can be obtained with maximum doses in such lesions as cervical carcinoma. By maximum doses one means the maximum amount which can be delivered without too great an incidence of permanent damage to other organs and which will still leave surrounding connective tissue in a sufficiently healthy state so that it may recover and react by proliferation. This is spoken of as massive dose therapy. This must be considered in terms of biological units and not in physical units. Unfortunately we have no method of correcting the variables, physical units and time into a biological unit product. For that reason, there has been a general tendency to standardize the time factor for x-ray and for radium in a dogmatic way to get rid of the variable time factor and to vary the biological dosage in terms only of physical units. This would recommend itself more to reason if there were sound experimental confirmation for a choice of time factor. With the exception of certain skin tumors and tumors of the larynx, pharynx and tonsil, there is no very clear cut clinical information to support the superiority of the single dose method of Wintz, the prolonged therapy of Coutard or the generally accepted American division for pelvic tumors of twenty-five to twenty-eight days. Many clinical investigators have chosen this and hold to it so as not to disturb the time factor. Physical units of dosage are then varied until a maximum dosage is determined which will, for example, produce not more than 2 per cent of rectal strictures or a 1 to 2 per cent primary radiation mortality.

Similar rules are applied to surface radiation therapy from radium or radon. An arbitrary time of 100 hours is chosen which is adhered to in all cases. The variables then are the number of milligram-hours and the distribution. Distribution is fairly adequately corrected by equivalent adjustment of the milligram-hour total so that biological dosage at the desired site is controllable by varying only one factor, the number of milligram-hours. For so-called surface irradiation with radium or radon, wherever possible, a standard focal distance of one centimeter is used throughout. By adjusting active radiation length and milligram-hours, a single factor is left and biological dosage may be adjusted by varying this.

It should be understood that by dosage, there is meant the only possible interpretation of that, which is the dosage delivered to the tumor or a chosen point related to it which is to be treated. It is just as silly to speak of x-ray dosage to a cervical carcinoma in terms of the number of physical units given to the skin of the abdomen as it would be to speak of the dosage to a surface tumor by radium in terms of milligram-

hours without reference to distribution, active radiation length or focal distance. To reduce it to the absurd is to compare it with the statement that the reading light from an electric lamp can be expressed in physical terms of the current flowing through it and quite irrespective of whether the material to be read be placed beside the lamp or across the street. This illustration may sound absurd and it is in most cases of x-ray dosage since those who use this form of therapy are skilled in its control. It is not absurd when applied to a large number of those who use radium and radon. These agents are more accurately controllable in the uterus, cervix and vagina than are x-rays. Known dosages are required and accurate charts are available for use. They are more honored by neglect than by use.

The conclusions are obvious. Each tumor and each patient must be individualized. The utmost possible accuracy must be applied and the various tools of accuracy must be used. It is only thus that the greatest possible salvage can be obtained.

A few interesting problems associated with specific gynecological tumors might be considered. These are chosen at random for their interest rather than any other reason.

The study of the origin of squamous cell carcinoma of the cervix has yielded no information comparable to that which has appeared from work on breast cancer. But a few bits of information are becoming clear. The old myth quoted from text book to text book that carcinoma of the cervix arises in cervical erosion has been exploded. This mistake was probably due to the fact that active erosion healing is all too often mistaken for carcinoma itself. Accurate study of early carcinomas show that, insofar as the genitalia, at least, are concerned, carcinoma does not arise in young but only in aging tissue. Primary squamous cell carcinomas are for practical purposes unknown in the squamous epithelium of polyps of the endometrium or cervix although carcinoma may become polypoid or may invade polyps. Neither is malignant degeneration seen in cervical erosions unless it has invaded them. But the great majority of early carcinomas arise in the old squamous epithelium at the margins of areas of erosion healing. The active repair processes associated with chronic inflammation do not pass over into malignancy. What effect the inflammation has in the production of malignant change in the surrounding tissue is not clear. It would be wiser to hold the idea of the relationship sub judice for the present.

Dr. Robert Meyer has also demonstrated by the study of very early carcinomas here that the tumor always arises from the basal cells over a limited area. Whether it begins in a single cell or not cannot be determined. The tumor grows by cell proliferation from this point, destroying the normal epithelium at the circumference and above. It can be readily diagnosed before it has ruptured the basement membrane. The old idea that the demonstration of invasion is necessary for a diagnosis of malignancy in such tissues has again been shown to be wrong. It might be pointed out at this point that leucoplakia of the cervix is not an obligatorily so-called precancerous lesion and that cancer cells may show a secondary leukoplakic change.

It might also be stated that histological classification of squamous cell carcinoma of the cervix has not proved to be the useful tool which it was once hoped that it might be. The cellular differentiation is a secondary quality. By comparison with the invasive qualities and the degree of extension which are shared by all histological types it can scarcely be said to be of any importance whatever.

There are three problems in cervical carcinoma for which no adequate answer is available. These are problems of the tumor in young people, arbitrarily stated as younger than thirty years, the problems of the adenocarcinoma of the cervix and that of the tumor, recurrent after treatment.

Carcinoma of the cervix in young women has the same clinical significance as that in the breast in a similar age group. Growth is rapid, metastases are early and recurrences almost the rule. It is not clear why this should be. The author has attempted to change this series of events by the use of daily fever therapy during treatment, post-treatment radon seeding and extension to very heavy dosage. No certain results have been obtained. At present, the department of Obstetrics and Gynecology at the University Hospital is carrying out Wertheim operation four weeks after the completion of therapy in operable tumors in this age group in order to get a series for evaluation. It is quite certain that this age group should be given a separate and very guarded prognosis.

Strange as it may seem, there is no accurate

information as to just what treatment is most productive, or what results can be obtained in adenocarcinoma of the cervix. Some clinics have reported no cures whatever while others rank the lesion as similar for purposes of treatment and prognosis to the squamous cell tumor. This confusion is likely due to three facts. It is often impossible to tell from histological diagnosis alone whether a given adenocarcinoma arose from the cervix or the uterine fundus. The later may extend to the cervix. The difference in natural history, treatment and prognosis are common knowledge. One suggests that many cured cervical adenocarcinomas were in reality adenocarcinomas of the corpus. Secondly, there is an adenoma malignum which occurs in the cervix. It is not as widely recognized as it should be. But it extends slowly and only locally in the majority of cases for a considerable period of time. These are comparatively readily curable and undoubtedly are included in some of the adenocarcinoma figures. Strictly speaking, they are adenocarcinomas and will destroy the host if untreated. But the inclusion of a neoplasm with such a different natural history as this, with the adenocarcinomas has not helped toward clear thinking in the latter condition. A third source of confusion lies in the fact that adenocarcinoma of the cervix is undoubtedly overdiagnosed. Squamous cell tumors may take an adenomatous-like form under a number of circumstances which are not worth detailing here. All of this makes it likely that the more pessimistic reports approximate reality. Adenocarcinoma of the cervix is being treated by radiation therapy followed by Wertheim operation in operable cases, in the hope of increasing the salvage.

The problem of local recurrence can lead only to the conclusion that some tumors, and they cannot be recognized before treatment by any means presently available, are as completely radio-resistent as the surrounding normal tissue. These tumor cells have been exposed to dosages, not in biological terms but in terms of the simple summation of x-ray and radium dosage, of the nature of between 15 and 25 erythema doses and yet survive. There is a suggestion that the surrounding tissue reaction may be at fault. All of us have seen tumors in cachectic patients treated by radiation. The tumor is readily sloughed away but scarring is absent, a crater remains and the tumor recurs. This is strong evidence that the healing of a tumor is in the final analysis a factor of normal tissue response, immunological response or some such factor. As has been suggested above, modern radiation therapy does not have as its primary aim the sloughing away of tumor but rather the interference with its reproduction, leaving the normal surrounding tissue in a state in which it can react. This should be the basis for dosage. It is assumed that healthy patients react similarly but there is no basit for such assumption and objective controls are lacking.

Under any circumstances, there is good basis for pessimism in attempts at repeat radiation for local recurrence and clinical experience lends bitter support to this view. Again, it focuses attention on the necessity for careful organization of the first attempt at treatment.

There is little to be said that is new or of promising interest in regard to carcinoma of the body of the uterus. It may seem trite to again state here that all uterine bleeding should be suspected of being due to malignancy until proven otherwise by histological means. It is hard to believe that any student could graduate without having attained that intellectual height. But they do. One thinks sometimes that ergot must have achieved first place in the treatment of this disease. Small bits of radium are applied in the delightful fancy that the lesion is a "functional bleeding," whatever that may be. And subtotal hysterectomies are done because a myoma is present. Adenocarcinoma in the cervical stump is not a nice disease.

This is perhaps the place to urge against the application of radium at the same time the diagnostic curettage is done. It is true that very often a diagnosis made on the gross material is correct. But it is also true that even frozen section reports on the same tissue are frequently in error. The same may be said of the negative diagnosis. Small doses of radium under these circumstances can only confuse the problems. And under any circumstances, radiation should for practical purposes never be used in the absence of an accurate diagnosis. This, the process of reaching a diagnosis in suspected malignancy, is the time to go slowly and carefully, taking only one step at a time as the way becomes clear.

It is becoming less and less likely as accurate information is obtained, that radiation therapy will constitute an acceptable primary atack upon adenocarcinoma of the uterine corpus. For about

five years the author has routinely subjected these patients to preliminary x-ray and radium radiation, followed in about four weeks by panhysterectomy. This allows accurate study of the results of the radiation. It has shown that with adequate x-ray and adequate distribution of the radium (which is not satisfied by a tandem applicator, be it noted), tumor which is confined to the surface has disappeared so far as microscopic study can determine. This does not necessarily mean that all tumor is gone.

On the other hand, tumor which has invaded the uterine muscle will sometimes show no morphological evidence of radiation effect. There is no way of determining which tumors have invaded and which have not. Tumor in the muscle is more dangerous than that on the surface since it is clinically silent. The operation carries only a 1 per cent mortality when very accurately controlled from the point of view of infection and offers in the operable cases a 60 per cent cure rate. The operative attack is still the standard method of treatment.

The department is planning very shortly to change the procedure at present employed and to substitute preliminary radium irradiation alone, followed by operation. It is likely that this will offer all of the advantages of the more thorough irradiation in the direction of cleaning up infection before operation. Under any circumstances, interesting comparable information will be forthcoming.

BRONCHIOGENIC CARCINOMA*

EDWIN J. SIMONS, M.D.
Swanville, Minnesota

BRONCHIOGENIC cancer has become the most interesting pulmonary disease of the present day. This is the result of three facts. In the first place, within a quarter of a century, cancer of the lung has developed from a rarity to a disease of comparative frequency. Secondly, as a result of its rise to prominence, thoracic surgery has become the treatment of choice rather than the court of last appeal. And thirdly, pulmonary cancer is to chest diseases what syphilis is to systemic syndromes, the great imitator. In order to present these and other features, a résumé of all aspects of pulmonary cancer will be outlined in this paper.

Historical Data

Bronchiogenic cancer can be traced back to the writings of Agricola in 1521. Mathesius, in 1559, and Pansa, in 1614, described cases which later were proved to be pulmonary malignancies. These were the Schneeberg mine cancers, and were not recognized by the authors as true pulmonary cancers. So, priority in describing bronchiogenic carcinoma belongs to Morgagni, who, in 1761, described a case in which necropsy revealed a cancerous ulcer of the lung. The second authentic pulmonary cancer was reported by Bayle in 1810. By 1878, the number of cases recorded in the literature, as reviewed by Reinhardt, had increased to twenty-eight. Since then, the number has gradually increased until at present the disease is no longer a rarity.

Incidence

Both the actual number of pulmonary cancers reported and a constantly growing literature on the subject reflect an increased frequency of these neoplasms. However, more than these evidences are required to determine whether the increased incidence is absolute or relative. Many investigators claim that the increased frequency is due to improved clinical acumen, greater interest in the disease, and increase in the number of postmortem examinations. Those who believe that an actual increase has occurred, maintain that the percentage increase of pulmonary cancers in all autopsies, and, above all, a percentage increase of pulmonary cancer in all cancers found at autopsy, prove irrefutably the reality of the increase.

In the United States, England, Germany, Switzerland, France, Russia and Argentina data have been presented proving both an increase of

*Presented at the joint meeting of the Mississippi Valley Conference on Tuberculosis and Mississippi Valley Sanatorium Assoc., St. Paul, Minn., Oct. 4, 1940.

pulmonary carcinomas in all autopsies and an increase in the percentage of all cancers found to be primary pulmonary cancers. Thus, then, a preponderance of evidence from widely scattered countries shows an absolute increase in the incidence of these neoplasms.

Etiology

In reviewing the causative factors, fourteen different etiologic agents have been found in the literature. Without exception, all of the suggested causes have one common quality, the production of chronic pulmonary irritation. Chronic irritation may be chemical, mechanical, bacterial, radio-active, or thermal. Several of the causes or possible causes may be classified under two or more of these headings, but all of them fall under at least one. Since the suggested causes are so diverse, the only conclusion possible is that irritation, which is common to all of them, is the real causative agent in the disease.

Pathology

From 75 to 90 per cent of these cancers arise in the large bronchi two or three centimeters from the tracheal bifurcation. These are known as the hilar or central type. The rest arise from the terminal bronchioles, and are known as peripheral pulmonary cancers. Their size varies from small outgrowths of the bronchial mucous membrane to tumors the size of a man's head. The larger tumors are soft and not unlike caseous tuberculous masses, sometimes with cavities filled with mucus, pus or necrotic material. Those containing many mucous glands are softer and more slimy than the others, as are also their metastases.

Within the past few years, the "oat-celled" tumors of the English have been reclassified as pulmonary cancers. At present, most of the superior pulmonary sulcus tumors are conceded to be cancers of the lung originating in the terminal bronchioles. Now, also, many endotheliomas of the pleura have been proved to be actual pulmonary carcinomas. The significance of these findings is that even within comparatively recent years, three pathological entities have been reclassified as pulmonary carcinomas.

Histogenically, also, much progress has been made in recent years. Previously, pulmonary carcinomas were thought to have three cellular origins: the bronchial epithelium, the bronchial mucous glands and alveolar epithelium. The present consensus of opinion is that all pulmonary cancers, regardless of the predominant cell type, arise from the basal cells. Consequently, the previous triad of origin has been replaced by the present unicellular concept.

Clinical Considerations

Symptomatology—All of these tumors arise within a bronchus, and, therefore, obstruction of the flow of air into or out of the lung becomes the principal mechanism in the production of symptoms. Two other factors in the cause of symptoms should be mentioned. First, as with cancer elsewhere, ulceration and hemorrhage are among the first evidences of these tumors. Secondly, the bronchiogenic cancer simulates a foreign body which nature is trying to extrude, so cough, either with or without sputum, is one of the most frequent manifestations.

The symptomatology may even suggest the location of the carcinoma. Cough and hemoptysis result from ulceration of tumors of the larger bronchi. In the peripheral tumors, cough either is entirely absent or occurs late as a result of pressure on a large bronchus. Paterson has stated that the blood-cough complex is characteristic of the central type, and pain is the early typical symptom of the peripheral type.

The frequency of symptoms in 1,456 cases so analyzed was as follows:

Symptom	No. Cases Analyzed	No. Cases with Symptom	Percentage Cases with Symptom
Cough	1376	996	72.3
Sputum	1217	822	67.5
Pain	1439	861	59.8
Dyspnea	1299	716	59.7
Emaciation	1187	573	48.2
Pyrexia	1112	477	42.8
Hemoptysis	1456	583	40.0

Other symptoms such as dilated veins, cyanosis, night sweats, vomiting, hoarseness and clubbed fingers occurred with varying frequency in less than 20 per cent of the cases. Thus, it is seen that cough occurs in three out of four cases; sputum, pain and dyspnea in three out of five; and fever and hemoptysis in two out of five cases. While emaciation occurs in almost 50 per cent of these patients it is usually a late manifestation and should not be expected early.

Certain symptoms or groups of symptoms should lead one to suspect the diagnosis. For instance, pain in the chest which is persistent

and not relieved by strapping should arouse suspicion. Dyspnea is one of the most frequent complaints that directs the patient with pulmonary cancer to the physician. One clinician has stated that hemoptysis is as suggestive of carcinoma of the lung in an adult as of tuberculosis in a younger person. In any atypical pulmonary disease in an adult, especially if characterized by cough, pain, dyspnea, or hemoptysis, pulmonary cancer should receive first consideration.

Physical Signs.—The most frequent early signs discovered by examination are decreased mobility of the chest, dulness or flatness extending outward from the hilus, and suppressed breath sounds. One day breath sounds are heard accompanied by râles while the next day either or both will have disappeared. This variability is characteristic of the disease.

On inspection, breathing is labored and chest movement lags or is absent. Unilateral limitation of expansion is frequently seen. If the disease has advanced far, asymmetry of the chest is present. When effusion is present, the intercostal spaces may bulge. In the late stages, the veins of the chest wall are distended, and edema of the face, neck, arms or hemithorax may be visible.

Tactile fremitus usually is decreased or absent on the diseased side. It may be increased on the unaffected side. The cardiac impulse is usually displaced toward the pulmonary lesion. Tenderness of the intercostal spaces can often be elicited. Enlarged glands may be palpated above the clavicles or manubrium sterni or in the axilla.

Percussion usually produces a dull sound, or, if obstruction is complete, a flat note. Dulness is often found an inch or two to one side of the sternum with a normal area between the dull space and the clavicle. Staehelin has said that a circumscribed area of dulness with decreased breath sounds and vocal fremitus indicated almost certainly the diagnosis of pulmonary cancer. Nowhere else in pulmonary diseases is found the hard stony resistance in percussion that is noted in pulmonary cancer.

In auscultation, the most typical finding is suppressed or absent breath sounds. When a tumor closes or fills a bronchus, collapse of the part of the lung supplied by that bronchus takes place. Then, breath sounds are absent and both vocal and tactile fremitus are diminished or absent.

Differential Diagnosis

Pulmonary cancer can simulate any intrathoracic disease. Consequently, any intrathoracic disease which does not run a typical course or which produces atypical symptoms or findings should lead one to suspect a bronchiogenic carcinoma.

Pulmonary cancer is to be differentiated from three groups of diseases: (1) those pulmonary diseases caused by micro-organisms; (2) those diseases involving the hilar and mediastinal structures; and (3) miscellaneous vascular and other lesions. In the first group are to be found tuberculosis, bronchiectasis, unresolved pneumonia, lung abscess, echinococcic cysts and mycotic diseases. Among hilar and mediastinal diseases to be differentiated from pulmonary cancer are Hodgkin's disease, lymphoblastomas, mediastinal gummas and abscesses. And in the third group are benign tumors, carcinoma of the trachea and esophagus, Pott's disease and tumors of the spine, and the various aortic aneurysms.

Since pulmonary cancer is most frequently mistaken for tuberculosis, some of the salient points in differentiating these two diseases should be mentioned. In tuberculosis, fever and tachycardia are usually present. They are absent except late in the course of bronchiogenic cancer or as a result of the complications it causes. Dyspnea is rare in tuberculosis, but frequent in cancer. In tuberculosis, there is usually little pain, yet this symptom is common in cancer of the lung, especially in the peripheral type. Tuberculosis makes its first appearance usually before the age of thirty-five; carcinoma appears most often after that age. Consequently, in tuberculosis appearing after the age of thirty-five, previous attacks can be elicited in the history.

Cancer usually spares the apices, whereas tuberculosis often involves them. Cancer is almost invariably unilateral, while tuberculosis is frequently bilateral. Impaired resonance with diminished or absent breath sounds is typical of cancer. Impaired resonance with bronchial breathing is characteristic of tuberculosis. In pulmonary cancer, the impaired resonance is flat, while in tuberculosis, it is dull. Râles are either seldom heard or are variable from day to day in cancer, but they are usually constantly heard in tuberculosis.

Laboratory and Other Diagnostic Aids

Pleural Effusion.—This occurs in from one-third to one-half of these cases. The fluid may be serous, purulent or bloody, and when it is the latter, pulmonary carcinoma is by far the most likely cause. None of the other effusions is so prone to fill the entire chest as is a cancerous one. Malignant cells can be demonstrated with sufficient frequency to make an examination of the fluid advisable.

Sputum.—In 1935, Dudgeon and Wrigley perfected a technic for the examination of sputum for cancer cells whereby they were able to demonstrate the histologic type of growth in twenty of twenty-six cases of proved pulmonary carcinoma. The finding of tubercle bacilli in the sputum does not refute the diagnosis of pulmonary cancer.

Roentgenology. — X-ray studies reveal two types of pulmonary cancer: the hilar or central, and the peripheral.

Hilar or central pulmonary cancers have two roentgenological characteristics that are of diagnostic importance. The first, hilar density, is unilateral, is roughly triangular with the apex pointing outward, and from the border strand-like processes radiate outward toward the lung periphery. This density usually lies opposite the space between the sixth and eighth ribs or at the level of the seventh rib posteriorly. The second characteristic, atelectasis, is a smooth, homogeneous density, anatomically limited and carrying the normal lung markings. The appearance of bronchiectasis, a mottled fan-shaped density at the costophrenic angle, also is suggestive of a bronchial tumor. In addition to these evidences, elevation of the diaphragm on the affected side, and displacement of the heart and mediastinum toward the pulmonary lesion are characteristic of atelectasis, and therefore suggest bronchial cancer.

In the less frequent peripheral type, the characteristic findings in the x-ray plate are either a solitary, round shadow in the lung field, or a massive involvement of one or more lobes. The solitary, circular form is recognizable as a dense, round area usually without the sharp-defined edge seen in the shadows of metastatic deposits. Such primary lesions are invariably single, which fact distinguishes them from metastatic growths. The massive lobar type appears as a complete consolidation of a whole lobe, less dense than fluid, without mottling of any kind nor with the varied texture seen in most cases of lobar pneumonia. The border or edge is an irregularly infiltrating one.

In fluoroscopy, Polevski has described the following triad of findings as pathognomonic of pulmonary cancer: (1) elevation of the diaphragm on the affected side; (2) paradoxical or "seesaw" movement of the diaphragm; and (3) pendulum movement of the heart toward the side of the lesion in inspiration and away from it in expiration.

Bronchoscopy.—Conclusive proof of the diagnosis depends upon biopsy, which is best accomplished by bronchoscopy. Early diagnosis by bronchoscopy is possible in 75 per cent of these cases.

Treatment

Aside from palliative measures, the treatment of pulmonary cancer is either surgical removal or irradiation. Many authors consider irradiation as palliative only; others maintain that it is potentially curative; still others regard surgery as the only possible means of cure.

Palliative measures may be directed to the patient's general well-being, to complications and sequelæ, or to specific symptoms. Pain is usually due to pleural involvement and may be relieved by sand bags and strapping. Heroic doses of opiates are often required. Artificial pneumothorax, injection of alcohol or section of the dorsal roots may be necessary to relieve pain. Dyspnea and cyanosis are caused by increased pressure within the pleura. Aspiration of the effusion frequently provides temporary relief. The sitting position and lying on the diseased side may improve the shortness of breath. Cough may be influenced only by antispasmodic cough mixtures or opiates.

Irradiation consists either of x-ray therapy or radon seed implantation into the growth. Many radiologists believe that such treatment is the most effective so far devised from both a curative and palliative standpoint. Some writers however contend that the radioresistant cells of pulmonary cancer make such treatment ineffective and that immediate, palliative results of irradiation are usually followed by a more rapid downhill course which terminates in death.

Surgical treatment is divided into curative bronchoscopic procedures and actual surgical excision. Eleven cures have resulted from bronchoscopic excision, cauterization or radium implantation. However, opinion prevails that the type of tumors for which such treatment can be used composes a minority of pulmonary carcinomas. Therefore, it appears that wide excision rather than bronchoscopic treatment would be the treatment of choice.

Surgical excision is accomplished by either lobectomy or pneumonectomy. It is in the technic and successes of thoracic surgery that some of the most remarkable advances have been made during the past few years. For instance, in 1920, Sauerbruch compiled fifteen surgical extirpations of the lung. In 1934, Heuer found reports in the literature of 225 lobectomies and pneumonectomies of which thirty-three were for pulmonary cancer. The present consensus of opinion concerning treatment of pulmonary cancer is that radical excision is the treatment of choice, and it alone offers a reasonable likelihood of cure.

In conclusion, mention should be made of the surgical personnel available to physicians practicing within the territorial boundaries of this society. Remarkable contributions to the field of thoracic surgery have been made by Alexander and Haight of Michigan, and by Graham of St. Louis. In fact, experienced and well-qualified thoracic surgeons are to be found in practically every state in the conference. Here in Minnesota, we are fortunate in having available as thoracic surgeons such widely recognized men as Kinsella, Wangensteen, Gardiner, Gray and Harrington.

BONE MARROW BIOPSY*

ROBERT HEBBEL, M.D.
Minneapolis, Minnesota

SINCE Seyfarth[29] (1923) described a method of trephining the sternum and particularly since Arinkin[1] (1929) introduced aspiration biopsy, examination of the bone marrow during life has become an accepted diagnostic procedure in diseases of the hematopoietic system. Sternal biopsy is by no means necessary in all hematologic conditions but is frequently a valuable source of information in those instances where the diagnosis cannot be established on the basis of the usual clinical and hematological findings. Certain more or less well-defined limitations to the method exist and only with regard to these limitations can the usefulness of sternal biopsy be properly evaluated. It is intended here to briefly outline the findings in the more commonly encountered hematologic conditions where examination of the marrow may be of aid to diagnosis and at the same time indicate certain of the difficulties in interpretation of these findings.

Methods

Examination of the sternal marrow is advantageous not only because of the accessibility of that bone but because the hematopoietic activity of sternal marrow is sustained throughout life (Custer and Ahlfeldt[4]) and in general is indicative of the character of the hematopoietic tissues as a whole (Stasney and Higgins[30]). Instances of irregularity of the composition of the sternal marrow may be encountered but material removed by biopsy may usually be considered representative.

Trephine biopsy consists in the removal of a plug of bone from the outer table of the sternum. The marrow adherent to its inner surface may be used for both imprints or smears and histologic sections. While this method affords excellent material for study, the required cutaneous incision is objectionable particularly if repetition of the biopsy is desirable or necessary. Furthermore, while the topographic relationships of the marrow are preserved in section, smears or imprints are indispensable for accurate identification of the various immature cells. Consequently the technically simpler aspiration biopsy has achieved greater popularity. Properly executed it causes but little more discomfort than does a venapuncture, leaves no scar and may be repeated as frequently as desired.

In aspirating marrow there is a certain amount of unavoidable dilution with sinusoidal blood.

*From the Department of Pathology and the Hematological Laboratory of the Department of Anatomy, University of Minnesota.

In hyperplastic marrows, and in any instance from accidental excess dilution, so few cells may be obtained that examination of the smears is very tedious and one may not be certain that the material observed is representative. In order to more uniformly provide adequate amounts of marrow for examination we have adopted at the University of Minnesota Hospitals a method of concentrating the cells obtained by aspiration. The technic is based on a method devised by Schleicher and Sharp[26] and further described by Limarzi.[16]

The sternal marrow may be approached either directly through the outer table of the manubrium or sternal body or through the sternomanubrial junction. All of these sites have been used but the sternal body in the third interspace or at the upper margin of the third rib is usually recommended. The structure of the sternum varies and no one site is satisfactory for all cases. The skin, subcutaneous tissues and periosteum at the elected site are infiltrated with procaine. A short 18-gauge spinal puncture needle is then forced into the bone at an angle of 45° (the point toward the head of the patient) until a sudden "give" indicates that the marrow cavity has been reached. The stilet is then removed and, with a tightly fitting, dry syringe (10 or 20 c.c. size), about 1 c.c. of material is aspirated. When the needle is properly placed the flow is prompt, steady and the patient usually experiences a "suction" pain. Unless such a flow is encountered the stilet is replaced and the needle shifted slightly in depth. If this maneuver repeatedly fails to result in a free return a new site is tried. Prolonged aspiration in the absence of a reasonably free return of fluid does not yield satisfactory material.

The aspirated material, composed of a mixture of sinusoidal blood, hematopoietic marrow and fat, is immediately transferred to a paraffined tube containing a minute amount of heparin as an anticoagulant. (Heparin is superior to other anticoagulants for it occasions less disturbance of cellular morphology.) A hematocrit tube is then filled with this mixture and centrifuged at from 2,000-2,500 RPM for five minutes. Centrifugation separates out the following layers reading from top down in the tube: (1) fat; (2) plasma; (3) myeloid-erythroid cells; (4) erythrocytes. The heights of the several layers are recorded. The fat and plasma are removed separately and discarded. The myeloid-erythroid layer, together with a small amount of the erythrocyte layer is pipetted off separately, transferred to a paraffined watch glass, mixed, and from this material smears are made and stained with the May-Grünwald-Giemsa combination. As originally described the method called for the preparation of smears from a mixture of equal parts of myeloid-erythroid, plasma and erythrocyte layers. Thus the supernatant plasma is removed to the point where the height of the plasma layer equals that of the myeloid-erythroid layer and then the remaining plasma, myeloid-erythroid layer and an equal portion of the erythrocyte layer are removed together, mixed and smeared. More cellular smears are obtained by taking only the myeloid-erythroid layer, and as this material is often rather tenacious, smearing is facilitated by adding a small proportion of the erythrocyte layer. The manner in which this step of the technic is employed is largely a matter of preference. Occasionally there is no grossly demonstrable myeloid-erythroid layer and in such cases the extreme superficial portion of the erythrocyte layer is removed for the preparation of smears for it will contain what nucleated cells are present.

Cellular Composition of the Marrow

In discussing the cellular composition of the marrow under both normal and pathologic conditions it is necessary to refer at least briefly to the question of terminology, for the existing differences in terminology in hematological literature are a constant source of confusion.

We employ that used by Downey.[8] For purposes of orientation it may be briefly stated that the myeloblast is the stem cell of the marrow under normal conditions. From it are derived: (1) granular leukocytes through leukoblast, promyelocyte, myelocyte and metamyelocyte stages; (2) erythrocytes through pronormoblast, basophilic normoblast, polychromatophilic normoblast and orthochromatic normoblast stages; (3) megakaryocytes. Megaloblasts are never found in normal marrow. With very few exceptions they are peculiar to pernicious anemia in relapse and develop from the myeloblast into the usual macrocytic erythrocytes through promegaloblast, basophilic megaloblast and the orthochromatic megaloblast stages.

The cellular composition of the marrow is expressed in several ways. Such calculations as

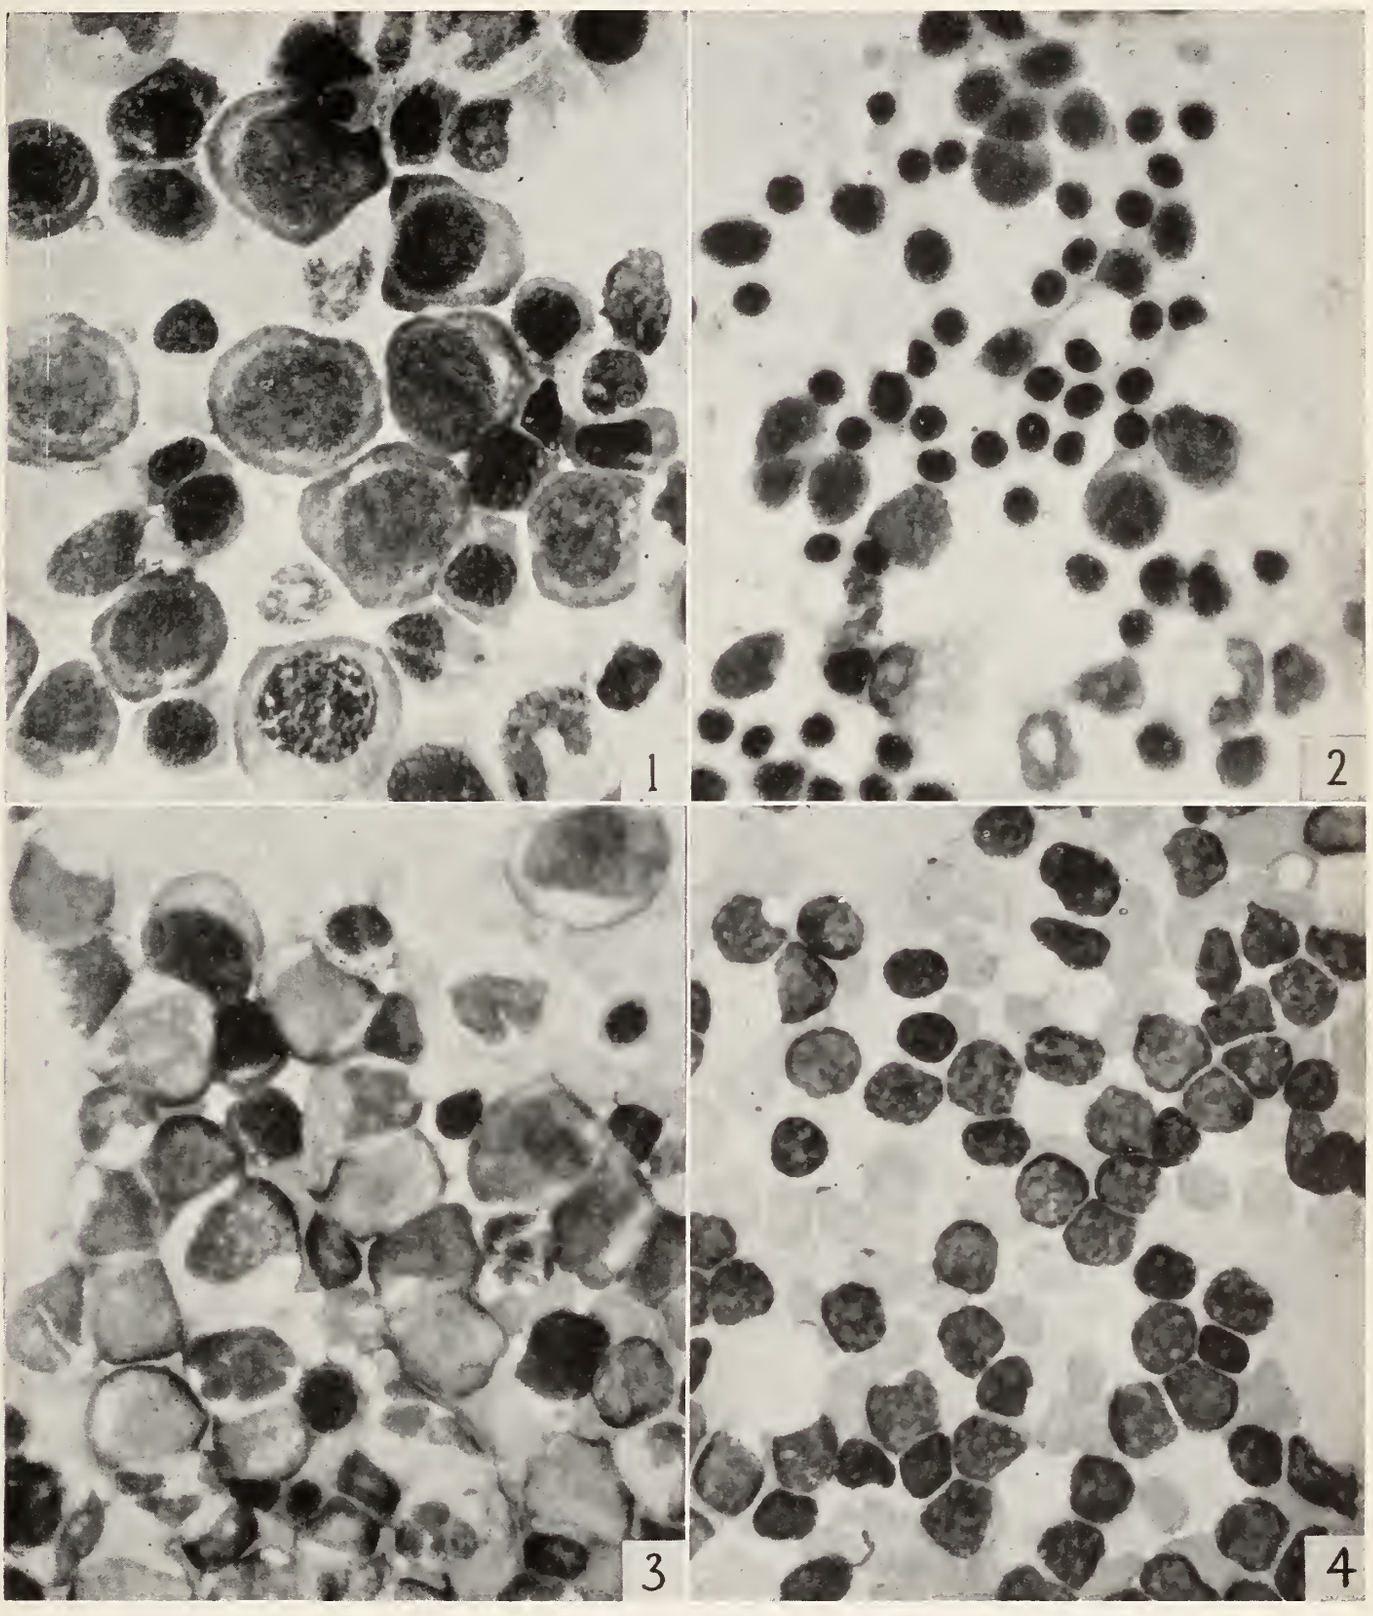
the myeloid-erythroid volume, the differential count, the myeloid-erythroid ratio and the maturity dispersion are all used in analysis by various writers.

The myeloid-erythroid volume (M-E volume) refers to the percentage of the total column in the hematocrit tube made up by the myeloid-erythroid layer of cells. This determination gives some information concerning the activity of the marrow but in any one instance is of limited value. Limarzi,[16] for example, found an M-E volume of 5 to 8 per cent in normal individuals, 1.5 to 3 per cent in aplastic anemia, up to 40 per cent in pernicious anemia, up to 75 per cent in chronic myeloid leukemia, etc. The M-E volume will vary not only with hyperplasia and hypoplasia of the marrow but with the amount of sinusoidal blood obtained at aspiration. Consequently an elevated M-E volume, while indicative of hyperplasia, may not express the actual degree of hyperplasia, and a reduced M-E volume may mean only excess dilution and not an actual hypoplasia.

The differential counts reported for normal marrows vary considerably, as any of the several collected tabulations of different authors will indicate (Scott[27]). Normoblasts, for example, constitute 12 per cent of the nucleated cells in one author's normals and 30 per cent in those of another. One author finds 3.5 per cent lymphocytes, another 24.9 per cent. Similar wide ranges are reported in the several myeloid categories. Megakaryocytes are usually estimated at much less than 1 per cent of the total. A very few reticulo-endothelial cells and plasma cells may be found.

The myeloid-erythroid ratio is the proportion of myeloid cells to erythroid cells. This value also varies from author to author. Limarzi[17] found the ratio in normal individuals to vary from 1.75:1 to 3.75:1. Stasney and Higgins[30] found a ratio of 1:1. The maturity dispersion refers to the percentages of the total myeloid and erythroid cells respectively made up by the several maturation levels in each group. These values also vary from author to author. As an example, Limarzi's values are shown in the accompanying tabulation (his terminology has been modified to correspond to ours).

Myeloid:	myeloblasts and promyelocytes	2.5%
	neutrophilic myelocytes	15-20%
	neutrophilic metamyelocytes	20-45%
	mature neutrophils	10-25%
	eosinophils (all stages)	2-5%
	basophils	Less than .5%
Erythroid:	pronormoblasts	Less than 5%
	basophilic normoblasts	20%
	polychromatophilic and orthochromatic normoblasts	75%



It is evident that the differential count, myeloid-erythroid ratio and maturity dispersons cover wide ranges as reported for normal individuals. Consequently only extreme alterations in these determinations are of significance. While the mathematical expression of the several values is very useful in detailed studies of the marrow under various circumstances, significant alterations, particularly as concerns the maturity dispersions, are apparent from examination of the smears and such calculations are in general unnecessary for diagnosis. Furthermore, just as in the examination of the peripheral blood, qualitative changes are of great importance. For example, the megaloblasts of pernicious anemia, and the abnormal myeloblasts (paramyeloblasts, monocytoid myeloblasts, etc.) peculiar to leukemia are frequently of greater importance than are quantitative changes alone.

The Anemias

The bone marrow of pernicious anemia in relapse is not only very hyperplastic but is also characterized by abnormal myelopoiesis and erythropoiesis. Normoblastic erythropoiesis is suppressed and largely replaced by megaloblastic erythropoiesis (Fig. 1). These megaloblasts are present in large numbers at various levels of maturation of which basophilic and polychromatophilic forms usually predominate. Megaloblasts are distinctly different from normoblasts and are characterized by a finer nuclear structure, more rapid accumulation of hemoglobin in proportion to the maturity of the cell, and usually by a larger size. The differences are recorded in detail and illustrated by Jones.[14] The marrow also presents immature stages of the characteristic pernicious anemia neutrophils of the peripheral blood (Downey[8]) in the form of large, hypersegmented neutrophilic promyelocytes, myelocytes, and metamyelocytes (Jones[13]).

Under the influence of liver extract the marrow rapidly undergoes profound changes. There is a rapid maturation of megaloblasts, no new megaloblasts are formed, and by the twelfth day only rare polychromatophilic and orthochromatic

megaloblasts may be found (Jones[14]). Coincident with this change there is a normoblastic hyperplasia, first characterized by the appearance of large numbers of pronormoblasts and basophilic normoblasts, which reaches its height prior to the maximum reticulocyte response of the peripheral blood but persists until hemoglobin and erythrocyte values of the peripheral blood approach normal levels. Pathologic neutrophils also disappear but much more slowly than the megaloblasts.

Aspiration biopsies of sternal marrow. May-Grünwald-Giemsa photomicrographs X 1000.

Fig. 1. Pernicious anemia in relapse. Note megaloblasts at various levels of maturation.

Fig. 2. Macrocytic hemolytic anemia showing normoblastic erythropoiesis.

Fig. 3. Acute myeloid leukemia. Maturing granulocytes as well as abnormal immature forms are present.

Fig. 4. Aleukemic lymphathic leukemia. Mature, uniformly small lymphocytes are shown.

In many cases of pernicious anemia the diagnosis may be established without resort to sternal biopsy. It is in those cases where the findings are atypical and not entirely diagnostic that biopsy is definitely indicated. The procedure permits a positive diagnosis in true pernicious anemia and eliminates the possibility in other macrocytic anemias. Most cases of pernicious anemia in relapse present a clearly diagnostic marrow. Cases in beginning remission—either spontaneous or induced—offer considerably more difficulty. The rapid disappearance of megaloblasts at the onset of remission has been noted. Under such circumstances exhaustive search may be required to demonstrate their presence. Here the immature forms of the pernicious anemia neutrophil have added significance, for their less rapid disappearance in remission may leave them as the only diagnostic feature of the disease. While the distinction between megaloblast and normoblast may be difficult on the basis of single cells, examination of the several maturation levels presented in the smears makes possible a definite statement as to whether the erythropoiesis observed is normoblastic or megaloblastic. It must be remembered that unusually large normoblasts (macronormoblasts) occur under a variety of circumstances, but that these cells maintain the morphologic features of the normoblast and resemble the megaloblast only in respect to size.

Contrasted with the megaloblastic erythropoiesis of pernicious anemia in relapse is the type of erythropoiesis seen in other anemias. As noted in idiopathic hypochromic anemia (Dameshek,[11] Segerdahl[28]), but equally characteristic of other anemias in which iron deficiency is the common denominator (hypochromic anemias of infancy, pregnancy, chronic blood loss and chlorosis) (Scott[27]), as well as in posthemorrhagic anemias, the macrocytic anemias other than pernicious anemia, and hemolytic anemias, there is a hyperplastic normoblastic marrow with relatively little disturbance, in the absence of infection, of granulopoiesis (Fig. 2). The qualitative features of the normoblasts may vary in these several conditions as may their maturity dispersions and the percentage of the nucleated cells which they comprise. The greatest normoblastic hyperplasia is seen in the hemolytic anemias, as in congenital hemolytic jaundice, where normoblasts may make up over 50 per cent of the nucleated cells (Weiner and Kaznelson,[32] Löwinger[18]). Megaloblasts are never found in these conditions and erythropoiesis proceeds along normal lines.

In aplastic anemias the described changes in the marrow vary with the individual author's concept of the disease. If extreme hypoplasia of the marrow is part of that concept, as expressed by Rosenthal[22] and others, then only such a marrow should be encountered. If the concept is based on clinical grounds a more variable condition of the marrow is found. Thus Rhoads and Miller[20] described marrows ranging from hypoplastic to hyperplastic. The term panmyelophthisis is often used synonymously with aplastic anemia but, as Schulten[25] points out, is best reserved for those cases in which extremely hypocellular marrows are demonstrable.

In acute aplastic anemia extremely hypocellular marrows are usually found. The M-E volume is very low, smears reveal but few myeloid cells and normoblasts, and lymphocytes frequently dominate the picture. Megakaryocytes are absent and there may be a few, commonly phagocytic, reticulo-endothelial cells and plasma cells. The condition of the marrow is well illustrated by the following case:

A white girl, nine years of age, was seen following a two-month period of weakness, persistent low-grade fever, purpuric episodes and a severe progressive anemia which had failed to respond to transfusions or other therapeutic measures. The peripheral blood contained 41 per cent hemoglobin (Sahli) and red and white cells numbered 2,050,000 and 2800 per cu. mm. respectively. The differential count revealed 95 per cent lymphocytes and 5 per cent neutrophils; there were no immature forms and both neutrophils and lymphocytes showed toxic changes. There were no reticulocytes. The cuff test was positive, the bleeding and clotting times were 30 minutes and 15 minutes respectively. Bone marrow aspiration was performed on two occasions. In each instance there was a grossly negligible M-E volume. The cells encountered were predominantly lymphocytes, most of which were leukocytoid. There were appreciable numbers of histiocytic reticulo-endothelial cells and a few plasma cells. Megakaryocytes were not found. There were a few polychromatophilic and orthochromatic normoblasts and the myeloid series was represented by rare myelocytes and metamyelocytes. In view of these findings a diagnosis of panmyelophthisis was made. At necropsy, a month after admission to the hospital, the marrow was like that found at the time of biopsy and there was no evidence of leukemia in any of the organs.

Chronic cases may show less disturbance of granulopoiesis, and erythropoietic activity varies.

There may be a distinct shift to the left in the maturity dispersion of the normoblasts, although, as indicated by consistently reduced M-E volumes, the hematopoietic activity is quantitatively suppressed. One case in which several biopsies were performed over a period of many months revealed variable degrees of normoblastic activity. It is probable that disappearance of hematopoietic marrow progresses unevenly in these cases and may account for some of the variations encountered. The activity of sternal marrow is ordinarily considered to be the most persistent of the entire hemotopoietic system (Custer and Ahlfeldt[4]), and it may appear active while that of the bulk of the blood forming marrow is more extensively suppressed.

Sternal biopsy is of distinct value in cases presenting the clinical picture of aplastic anemia. The changes in the marrow in symptomatic aplastic anemia which is the result of known toxic agents such as benzol, x-irradiation, prolonged infections and the like, are similar to those of the idiopathic form. The findings are, however, quite different when the anemia is produced by an aleukemic leukemia or a carcinomatosis of the bone marrow. If one encounters a cellular marrow in a clinical aplastic anemia the possibility of a remission is perhaps greater and in this sense may be of some value in predicting the course of the disease.

Agranulocytosis

In agranulocytosis the myeloid series alone is involved and erythropoiesis is not suppressed. Custer[3] and Fitz-Hugh and Krumbhaar[9] described failure of maturation and proliferation of myeloblasts. Darling, Parker and Jackson[7] described hyperplasia of stem cells and absence of more mature forms in rapidly fatal cases, hypoplasia of myeloid cells coincident with the appearance of many plasma cells and lymphocytes in fatal cases of longer duration, and rapid maturation during the recovery phase of favorable cases. Jaffé[11] emphasized degenerative changes in the myelocytes. Rohr[21a] described three types of marrow in agranulocytosis: (1) Severe cases with complete granulopoietic aplasia accompanied by proliferation of reticular cells (phagocytic, lymphoid and plasma cell types); (2) moderately severe cases with the marrow hyperplastic at promyelocyte-myelocyte levels; (3) mild cases with an essentially normal marrow but showing some reduction in metamyelocytes and band forms. Biopsy of the marrow is of some prognostic significance in this disease, for the cases with complete granulocytic aplasia have a less favorable prognosis than do those with cellular marrows.

Essential Thrombocytopenic Purpura

In essential thrombocytopenic purpura the marrow shows little disturbance of granulopoiesis, and erythropoietic activity varies somewhat with the degree of anemia that may be present. Studies of the marrow in this condition have been particularly concerned with the megakaryocytes. There is a notable increase of these cells according to Jaffé,[12] Rohr,[21b] Limarzi and Schleicher,[17] and others. Pathologic changes, particularly lack of granulation, were described by Frank,[10] Schminke,[24] and others. Markoff[19] considered quantitative estimations to be unreliable and found the same morphologic features in normal marrows as in this disease.

In the very few cases in which we have studied the marrow, the adult forms have not appeared to be more numerous than in many other marrows but young forms were more readily found. Morphological changes were not impressive. The practical value of biopsy in this disease is not significantly influenced by disagreement concerning the morphologic features of the megakaryocytes. Biopsy helps to separate this condition from other diseases, such as acute aplastic anemia and aleukemic leukemia, which may present a similar clinical picture. Wiseman, Doan and Wilson[33] listed biopsy of the marrow as one of the required diagnostic procedures.

Leukemia

Biopsy of the marrow yields no information of diagnostic importance in cases of leukemia presenting typical clinical and hematological findings. Biopsy is indicated in suspected cases in which positive evidence from other sources is lacking. Many cases present clinical features not unlike those of aplastic anemia, purpura, agranulocytosis, pernicious anemia, et cetera. Aleukemic and subleukemic phases of the disease are not uncommon, and under such circumstances sternal biopsy may immediately provide a diagnosis which would otherwise require an extended period of observation.

Chronic myeloid leukemia with a peripheral leukocytosis presents a myeloid hyperplasia with a maturity dispersion more or less approximating that of the peripheral blood (Segerdahl,[28] von Jagic and Klima,[31] Scott[27] and others). Thus, although there is commonly a significantly elevated M-E volume, there may be no significant deviation from the normal maturity dispersion. The diagnosis in an aleukemic state is consequently difficult. Schulten[25] and Barta[2] emphasized the similarity of these marrows to those observed in certain chronic infections. Many toxic-infectious states are accompanied by myeloid hyperplasia with variable degrees of shift to immaturity. Thus such a marrow might be predominantly myelocytic or myelocytic-promyelocytic and indistinguishable from that of a leukemic marrow presenting a preponderance of cells at the same levels of maturation. The fact that infections are frequently accompanied by increased numbers of reticulum cells and plasma cells as well as toxic changes in the leukocytes, features usually absent or less prominent in leukemia, is of aid in differentiation (von Jagic and Klima[31]).

In most cases of acute myeloid leukemia there is a great preponderance of immature forms—myeloblasts (Segerdahl,[28] Schulten,[25] Dameshek[6]). Schartum-Hansen,[23] Scott[27] and others emphasize the frequent abnormal morphological features of these immature leukemic cells. These forms are the paramyeloblasts of Naegeli, micromyeloblasts, monocytoid myeloblasts, etc. Such a marrow is clearly diagnostic irrespective of the blood picture. Klima[15] described three types of marrow in acute myeloid leukemia: (1) hyperplastic with about 90 per cent of the cells at myeloblast level; (2) hypoplastic but with a similar proportion of stem cells; (3) hyperplastic but with variable degrees of immaturity (Fig. 3). Cases in the third group are not rare and offer considerable difficulty in diagnosis. These marrows are again not unlike the hyperplastic reactions to infections. Barta,[2] for example, described marrows with high proportions of stem cells in specific infections accompanied by severe leukopenia. We have observed several cases in which it was extremely difficult to determine whether the findings represented a reaction to an infection, symptoms of which these patients so frequently exhibit, or a leukemia. In one case, with the clinical features of sepsis, in which repeated examinations of the blood revealed only rare immature cells, the marrow showed but little shift in the maturity dispersion and the immature forms were not sufficiently abnormal to be considered diagnostic. The importance of the qualitative features is illustrated by the following case:

A white female infant, five months of age, was admitted to the hospital one month after the onset of a persistent upper respiratory infection and ten days after the appearance of a swelling behind the right ear. The pertinent findings were: moderate pallor, temperature of 101.4°, fluctuant postauricular mass, thick, reddened right tympanic membrane, and palpable liver and spleen. In the peripheral blood the hemoglobin was 52 per cent (Sahli) and red and white cells numbered 2,800,000 and 14,100 per cu. mm. respectively. The post-auricular subperiosteal abscess was drained and a right myringotomy was performed. The hemoglobin rose to 90 per cent following transfusions. Postauricular drainage persisted for a time but the wound finally healed and the fever temporarily disappeared.

At the time of admission the differential count on the peripheral blood revealed 50 per cent lymphocytes, 20 per cent neutrophils and 30 per cent monocytes. Both neutrophils and lymphocytes showed toxic changes. The monocytes were mature although some were atypical. Whether the picture presented was one of a monocytic response to an infection or a monocytic leukemia was uncertain. Aspiration biopsy on the tenth hospital day yielded a cellular sternal marrow with a myeloid maturity dispersion which, although shifted to the left, was not quantitatively significant. There were, however, numbers of abnormal monocytoid myeloblasts. These cells were of variable size, had variable amounts of cytoplasm both with and without azure granulation, and had abnormally lobulated nuclei. Mature monocytes were not found. Toxic-infectious features such as increased numbers of plasma cells and histiocytes were absent. It was believed that although the marrow could hardly be said to present irrefutable evidence of leukemia, the abnormal immature forms, together with the peripheral monocytosis and splenomegaly, justified a diagnosis of monocytic leukemia (Naegeli type). At necropsy, ten weeks after admission to the hospital, the typical findings of myeloid leukemia were presented.

It is evident that the findings in both acute and chronic myeloid leukemia are extremely variable. While the diagnosis in the presence of pronounced changes is readily made, the dividing line between a leukemic and a "reactive" marrow is by no means sharply drawn. Attention to the qualitative features, such as abnormality of the cells, toxic changes, et cetera, is

helpful, but the findings are frequently subject to interpretation, may be justifiably interpreted only in connection with the clinical features, and it may even then be impossible to make a positive diagnosis.

The typical case of lymphatic leukemia with a high peripheral lymphocytosis yields a marrow in which about 90 per cent of the cells are lymphocytes (Segerdahl,[28] Klima[15]). It has been pointed out that under such circumstances it is impossible to determine the proportion of lymphocytes derived from the marrow and diluting sinusoidal blood respectively. When the peripheral blood contains from 10,000 to 20,000 cells per cu. mm. the marrow usually shows from 30 per cent to 50 per cent lymphocytes (Rohr,[21] Klima[15]). Yet in this group as well as in cases without elevated peripheral counts the degree of lymphocytosis of the marrow varies greatly. Scott[27] found from 7 per cent to 97 per cent lymphocytes in cases presenting low to moderately elevated peripheral counts.

Probably most cases will present a sufficiently high proportion of lymphocytes to be considered diagnostic. In these instances the procedure is an easy means of establishing or confirming a diagnosis as illustrated by the following case:

A white woman fifty-one years of age, gave a history of gradually progressive weakness of a year's duration and severe headaches during the last three months of this period. The only significant physical finding, in addition to marked pallor, was the presence of palpable posterior cervical, axillary and inguinal nodes. The hemoglobin was 20 per cent (Sahli); red cells and white cells numbered 990,000 and 4,500 per cu. mm. of blood respectively. There were 70 per cent of lymphocytes and 30 per cent neutrophils by differential count; there were no immature forms and the neutrophils presented a moderate toxic granulation.

Sternal aspiration yielded a cellular marrow completely overrun with uniformly small mature lymphocytes (Fig. 4). This finding, together with the data previously presented, entirely justified a diagnosis of aleukemic lymphatic leukemia.

Cases without significant lymphocytosis in the marrow do occur and a diagnosis on the basis of a sternal biopsy may be impossible. Such instances have been reported by Weiner and Kaznelson,[32] Klima[15] and others. In one of our cases of aleukemic lymphatic leukemia, proven at autopsy, three biopsies of the sternal marrow failed to reveal evidence of the disease.

The degree of lymphocytosis necessary for a positive diagnosis is subject to interpretation. Scott[27] considered 40 per cent lymphocytes diagnostic. It has been noted above that reported normal counts range up to 24 per cent, although few are above 12 per cent. Although a large percentage is necessary for an arbitrary diagnosis, a less marked but elevated lymphocyte count must be viewed with suspicion, and in conjunction with the clinical and other hematological data may at times justify a diagnosis. The differential count alone is of little significance. Scott reported up to 80 per cent lymphocytes in cases of aplastic anemia and the case cited above under that topic is similar. In such instances, however, the lymphocytosis is relative, for the marrow is extremely hypocellular. In the absence of a demonstrable cellular marrow indicated either by large numbers of cells in direct smears or a reasonable M-E volume, a diagnosis of lymphatic leukemia must be made with caution. The qualitative features are also of importance. Small numbers of immature lymphocytes are of greater significance than an equivalent proportion of mature forms. Chronic cases present the same monotonous uniformity of the cells as is exhibited in the peripheral blood. Toxic changes, as noted under myeloid leukemia, are usually absent. Irregular involvement of the marrow undoubtedly accounts for failure to demonstrate the disease in some instances, and when a biopsy in a suspected case gives negative results, repetition of the procedure at a different sternal level may be worth while.

Summary

Sternal biopsy is a useful procedure in the diagnosis of diseases of the hematopoietic system. While in many instances biopsy is unnecessary and can add no information of diagnostic importance, it may be very helpful in obscure cases. The indications can hardly be arbitrarily defined, but biopsy may be considered advisable in any case where a disease of the hematopoietic system is present or suspected and the evidence from other sources does not permit a diagnosis. Biopsy is particularly advisable in obscure anemias, suspected leukemias, thrombocytopenic purpura and agranulocytosis. The findings may or may not be conclusive, are frequently subject to interpretation, and the procedure can by no means be considered to give the final answer to

all hematological problems. An appreciation of its limitations increases the value of sternal biopsy as a diagnostic aid.

NOTE: Thanks are due Dr. C. J. Watson and Dr. Irvine McQuarrie of the Departments of Medicine and Pediatrics respectively, of the University of Minnesota Hospitals, for permission to use the clinical data in the cases reported here.

PNEUMONIA IN DULUTH DURING 1939-1940*

WILLIAM D. COVENTRY, M.D.
Duluth, Minnesota

THE mortality from pneumonia is decreasing. The factors responsible for this are not definitely known. Is the widespread use of sulfapyridine responsible? Is the disease changing its form due to alterations in the virulence of the organisms or to increased resistance in the host? Other infectious diseases are also showing lower mortality rates, and one wonders how much is due to improvement in diet, sanitation, housing, etc. Reimann[5] discusses this question but is unable to come to a definite conclusion as to the relative importance of any one of these factors. Chemotherapy, however, must be considered a major determinant.

In order to study the current form of pneumonia and its response to therapy, particularly chemotherapy, a hundred unselected cases occurring in Duluth hospitals† during the 1939-1940 season were reviewed. The clinical records and x-rays were examined so that only those with definite infiltration or consolidation were included. Complicating pneumonias such as postoperative or hypostatic were excluded. The salient features brought out by this study will be presented.

Clinical Features

The monthly incidence was not unexpected, the greatest number of cases occurring during the months of March and April.

The symptoms of the present illness could

*From the Department of Internal Medicine, The Duluth Clinic. Presented before the Interurban Academy of Medicine, May 15, 1940.

†St. Mary's Hospital, St. Luke's Hospital, Miller Memorial Hospital.

be dated back to an upper respiratory infection in 60 per cent of the cases. In half of these it extended back as far as two weeks. While the individual was suffering from such symptoms as malaise, cough, slight fever, etc., there would suddenly occur a chill with pain in the chest and the actual onset of the pneumonia take place. In 30 per cent of the cases the onset was precipitate without antecedent symptoms of upper respiratory infection.

The appearance of the patients at the bedside was not striking. They usually did not appear profoundly ill and stertorous breathing with marked prostration and dyspnea were uncommon. Abdominal distention was also seen rarely.

Practically all types of pneumococci were encountered in the sputum. Fifty-one per cent had a positive pneumococcus typing, 23 per cent had a negative typing reaction, and 26 per cent were not typed. Of those having a positive reaction, 70 per cent had pneumococci of the "lower types" (I, II, III, VII, and VIII). In view of the 23 per cent who had a negative typing reaction it is probable that some cases are included in this series which are not due to the pneumococcus but to some other organism or virus.

Pathology

The classic pathology of pneumonia consisting of congestion, infiltration, consolidation and resolution is well known. Experimental lobar pneumonia has been produced and the pathogenesis elucidated. The organisms penetrate the bronchial wall and invade the peribronchial lymphatics. Congestion and edema of the peribronchial tissues occurs and the organisms travel peripherally by the peribronchial route until they reach the alveoli. Finally when the organisms lodge in the alveoli a fibrinous exudate is formed and the familiar changes of consolidation are produced. It is seen then that the initial infection begins centrally and spreads out by infiltration. When this spread goes into a single lobe of the lung and the entire lobe becomes eventually involved we have the typical picture of lobar pneumonia. However, if only part of a lobe is involved or if parts of several lobes are involved, the distribution is lobular and the term, lobar, if strictly applied, is incorrect. In the cases studied, all these pathological variations were observed either at autopsy or by radiograph.

The distribution of the lesions was widespread in some cases and so minimal in others that they could scarcely be seen. A single focus of pneumonia was observed in fifty-six cases, two foci in twenty-seven, three foci in eight, four foci in one case and six foci in 1 case. No radiographs were taken in seven cases. So-called migratory pneumonia was seen in three instances. In one of these there was a fatal termination.

Complications were very uncommon and when they did occur were extremely mild. Small effusions were present in five instances. There was one empyema. This was easily treated by repeated aspiration and recovery was uneventful.

Therapy

The treatment of each case was recorded. This was made easy by the fact that 90 per cent of the cases were routinely treated with sulfapyridine, alone, or with the addition of serum, oxygen, x-ray or diathermy. A few were treated with sulfanilamide, neoprontosil and sulphathiazole. The effect on the temperature curve was used as an indicator of the potency of the treatment. Because of the low mortality rate and the relatively small number of cases studied, it was felt that the mortality rate would not be an accurate criterion. No serious or fatal toxic reactions occurred.

Sulfapyridine.—The drug was used in 90 per cent of the cases. It was either used alone or in combination with serum, oxygen, diathermy or x-ray. No essential difference in results was noted whether used alone or in combination. In 75 per cent of cases there was a prompt drop in temperature to normal in one and one-half to two days. In the 25 per cent in which this did not occur the drug was either given in insufficient dosage, the extent of the involvement was very great, or the patient was admitted in a terminal state.

The usual dosage was 2 grams stat. with 2 grams repeated in four hours and 1 gram every four hours thereafter. This was continued until the temperature was normal. At this time the drug was usually stopped and there would result a rebound of the fever with a delayed return to normal. In many instances, especially in those where the fever failed to return to normal promptly, a lower dosage such as .65 grams every four hours or 1 gram every four hours was prescribed. This is considered insufficient dosage by

most authorities. It would appear that the optimal dosage is 2 grams stat. and 2 grams in four hours with 1 gram every four hours thereafter. When the temperature reaches normal, the amount should be decreased to 0.5 gram every four hours, later to 0.5 gram every six hours and finally discontinued. With this method toxic reactions are minimal and no rebound of temperature occurs. Higher dosage is always associated with more reactions and results which are no better.[1] In many cases a smaller dosage will be effective. As with all drug therapy it is probably unwise to adhere rigidly to one definite system of dosage but one should in general give "enough." It is probably safest to drive the temperature to normal as soon as possible and keep it there if this can be accomplished without undesirable reactions. As has already been mentioned, there is a tendency for the pneumonia to become migratory in some instances. The prompt administration of enough of the drug to quickly drive the temperature to normal might prevent this.

Sulphathiazole, neoprontosil and *sulfanilamide* were used in a few cases but the number was so small that no conclusions could be drawn. Oxygen was administered in only eighteen cases, and always with other therapy. This may be an indication of the relatively mild form of the disease present. Diathermy and x-ray were used in eleven instances. They were never used alone but only when other agents failed to bring a rapid favorable response.

Serum—This therapy was used in only eight cases and in these sulfapyridine was also given. There were four cases of Type I, three cases of Type III and one case of Type II. The results of the combined therapy seemed no different from those where sulfapyridine alone was used. It was often noted that by the time the sputum had been typed, serum ordered and sensitivity tests made, the temperature had already fallen to normal because of the sulfapyridine which had been given immediately on admission. Finland[3] recommends the use of serum combined with sulfapyridine and there is experimental work to show the superiority of this over sulfapyridine alone. However, Dowling[2] in a series of 220 cases found a lower mortality when sulfapyridine was used (11 per cent) than when serum alone was used (16.7 per cent). Finland had a mortality rate of 13 per cent for patients treated with serum alone and 15 per cent for those treated with sulfapyridine alone. In the cases that received early treatment Dowling noted a mortality of 10.8 per cent when serum was used and 2.9 per cent when sulfapyridine was used. It is seen that the figures for each type of therapy are almost the same. The good practical results seen with sulfapyridine combined with the inexpensiveness and ease of administration seem to warrant its further routine use.

Mortality

There were five deaths encountered in the hundred patients studied. When one considers the fact that these patients were from all walks of life, both urban and rural, and that they were treated by various doctors in different hospitals, this mortality rate is admirably low. It is also noteworthy that there were no deaths in uncomplicated cases, which were seen early. A brief description of the fatal cases follows:

Case 1.—An eighty-two-year-old male was admitted in a semi-stuporous and delirious condition. Prontosil and sulfapyridine were administered with some difficulty. He died seven days after entering the hospital. The sputum was not typed. Autopsy showed bronchopneumonia in the left upper, right upper and right lower lobes, and a recent embolism in the right lower pulmonary artery. This might be looked upon as a terminal bronchopneumonia but no other disease complicated the picture, except possibly senility.

Case 2.—This patient, a sixty-year-old male, was in extremis on admission and died about twelve hours later. He had a positive Kolmer and Kline blood reaction. No autopsy was obtained.

Case 3.—This patient had a migratory pneumonia. mococcus was recovered from the sputum. There was an old history of pernicious anemia but no anemia was present at this time. She was treated with varying She was sixty-five years of age. A Type XXIX pneuamounts of sulfanilamide, neoprontosil and sulfapyridine. After many febrile recurrences she finally began to improve. This was interrupted by a final rise in temperature with heart failure and death. The autopsy showed a right empyema, a large infarct in the right lower lobe, and an organizing bronchopneumonia throughout various parts of both lungs.

Case 4.—This patient, aged seventy-seven, was admitted in coma. He had in addition to pneumonia, uremia and uncontrolled diabetes. An autopsy showed a bronchopneumonic consolidation in the right and left lower lobes. There was no kidney pathology.

Case 5.—This sixty-year-old male was admitted in a stuporous condition. He had had asthma for many years and had been a heavy drinker. His pneumonia was Type II. Heavy sulfanilamide and serum therapy were given but he died in two days. The autopsy showed consolidation of the right lower lobe, fatty

vacuolization of the liver, grade III and thickening of the basement membrane of the bronchioles.

It is seen that the deaths, at least four of them, might be due to the poor condition of the patient at the time of admission to the hospital. Complicating conditions such as fatty liver, uremia, diabetes, cerebral arteriosclerosis were also factors in the mortality.

Comment

The pneumonia seen in Duluth during the past winter has been of a comparatively mild type. The generally favorable course and mild symptoms in many of our cases suggests the possibility that we are dealing with a different type of disease than that seen formerly or from that seen in metropolitan areas. Murray[4] in Boston has recently described an atypical bronchopneumonia which has some features in common with our cases. He noted that in about 50 per cent there was an onset with symptoms of "flu" or "cold" and about one-fourth had a sudden recent onset. The physical findings in the chest were minimal. Sputum was scanty. There was no tympanites. This syndrome was also seen in many of our patients. A comparison of the x-ray findings also shows some similarities. He noted a lobular distribution with most involvement in the lower lobes but the upper middle and hilar areas were also affected. This we have seen. However, bilateral lesions were only observed in 10 per cent and in our cases they were present in 30 per cent. He found varying numbers of one or more types of pneumococcus but practically none of the "lower types." Seventy per cent of our cases with positive sputum had pneumococci of the "lower types." It would appear that the atypical bronchopneumonia or acute interstitial pneumonia described by Murray and others is not exactly similar to that seen in this locality but some of our cases correspond.

Dowling in Washington, D. C., reported on 232 cases of pneumonia in the 1938-39 season. Of ninety-six patients treated with serum alone there was a mortality rate of 16.7 per cent. Of 136 patients treated with sulfapyridine alone there was a mortality rate of 11 per cent. This includes all cases early and late. Apparently sulfapyridine has a slight lead over serum in therapeutic effectiveness. If only those patients who were treated early are included the figures are 10.8 for the serum-treated and 2.9 for those receiving sulfapyridine. This early treated group probably compares with the type of case observed in our Duluth hospitals. Therefore our mortality is roughly comparable. In the larger cities more late cases are admitted to the hospitals and therefore their mortality rates tend to be greater.

Conclusions

1. One hundred cases of pneumonia appearing in Duluth during the 1939-40 season were analyzed.
2. The disease was of a comparatively mild nature with few complications. The most prominent feature was the tendency for the pulmonary involvement to be of a lobular character, multiple foci being present in nearly half the cases.
3. Sulfapyridine was used in 90 per cent of the cases. As a rule a prompt fall in temperature occurred. When this was not the case insufficient dosage of the drug was usually responsible.
4. There was a mortality rate of 5 per cent.

HYPOTHYROIDISM IN CHILDREN

Physicians often have difficulty in diagnosing hypothyroidism in children. One of the commonest errors is to think that mongolian idiots are cretins. Many times mongolian idiots referred by practicing physicians to children's clinics arrive with the diagnosis of cretinism. Mentally defective children are often considered to be cretins, solely because of their retarded mental devlopment and particularly if they happen to have a puzzled expression and queer physiognomy. Dwarfism, even if not accompanied by any of the stigmas of hypothyroidism, is often thought to depend on deficiency of the thyroid, probably because hypothyroidism is so well known as a cause of dwarfism. An error which has become common recently is to consider delay in the development of the centers of ossification of the epiphyses as being due to hypothyroidism. This is the outgrowth of the mistaken idea that the thyroid alone governs the maturation of the centers of ossification of the skeleton. The principal difficulty is that the physician is inclined to base the diagnosis of deficiency of thyroid on the finding of one or two suggestive signs. The paper of Wilkins and Fleischmann which appears in this issue of *The Journal* is timely. It indicates the necessity of considering the entire clinical picture from the point of view of both functional and structural changes. Attention is drawn also to the fact that the character and extent of structural changes depend on the time of life when the deficiency occurs and the length of time it remains untreated.—*Jour. A.M.A.,* May 31, 1941.

AN ATTEMPT TO PREVENT POSTOPERATIVE PNEUMONIA WITH A RESPIRATORY VACCINE*

WILLIAM J. TENNISON, M.D.
J. ARNOLD BARGEN, M.D.
and
HARRY G. WOOD, M.D.
Rochester, Minnesota

NUMEROUS measures to reduce surgical risk in intestinal operations have been developed through the years. One of these efforts has been an attempt to prevent infections of the upper part of the respiratory tract. With the advent of cold weather, vaccines of streptococci and pneumococci were administered for several days to a week before undertaking such operations. During the years of this method of treatment singularly few instances of postoperative pneumonia occurred on the intestinal service.

However, in the summer of 1937 postoperative pneumonia developed in several cases while the patients were in a hospital under exceptionally well-controlled circumstances. It had been concluded by various investigators that immunity could be produced in human beings and animals with vaccines prepared from heat-killed streptococci and pneumococci.[1,2,3,7] These investigators felt that protection had been afforded to persons against epidemic infections of the respiratory tract and to animals against inoculation of streptococci isolated in these diseases by the use of composite, relatively nontoxic vaccines prepared with the streptococci and pneumococci concerned. The cataphoretic velocity and pneumotropic virulence of streptococci isolated in studies of the common cold, of influenza and of simple and influenzal bronchopneumonia, as studied by Rosenow, are characteristic and much alike in different seasonal epidemics.[4,5,6] It had been thought that a vaccine prepared from these organisms might afford protection against postoperative pneumonia.

For this reason such a vaccine was administered to patients on whom intestinal operations were to be performed. The patients who were to have such operations received pre-operative preparation on the combined colon service in the hospital for several days. It seemed, therefore, that an excellent opportunity to establish the value of a respiratory vaccine was at hand. A minimum of three pre-operative days to administer the vaccine to the patients was available. The vaccine used was prepared by Dr. E. C. Rosenow from strains of streptococci and pneumococci which had been isolated from patients having acute infections of the respiratory tract, chiefly the autumnal cold and influenza. The vaccine was made to contain 2,000,000,000 heat-killed (70°C., one hour) organisms per cubic centimeter of many freshly isolated strains that had been preserved for some time in dense suspension of glycerol (two parts) and 25 per cent salt solution (one part). Three-tenths cubic centimeter of the vaccine was injected subcutaneously two days before operation, 0.5 c.c. the day before and 1.0 c.c. the day of operation. There was only slight local reaction and no untoward constitutional reaction. The cases were studied postoperatively and the necessary clinical, roentgenologic and special studies were carried out to determine the presence of frank pneumonia.

Because of the variety of intestinal conditions and operative procedures, it was decided that alternate patients should receive the vaccine. This was done by arranging the list of cases scheduled for operation three days hence in numerical order beginning with the smallest clinic registration number. Whether or not the first patient on the list for a given day received vaccine depended on the last patient on the list of the day before. Analysis confirmed the randomness of this sample.

Table I shows the incidence of postoperative pneumonia among patients who had received vaccine and among those who had not received it. Under the conditions of observation as outlined the vaccine did not seem to lower the incidence of frank postoperative pneumonia. We therefore decided to study the characteristics of the group of cases with respect to age, sex and other pertinent factors.

*Work done on Intestinal Service, St. Mary's Hospital, Rochester, Minnesota. From the Mayo Foundation (Tennison, Fellow in Surgery) and the Division of Medicine, The Mayo Clinic (Bargen and Wood).

TABLE I. INCIDENCE OF POSTOPERATIVE PNEUMONIA AMONG PATIENTS WHO HAD RECEIVED VACCINE AND AMONG THOSE WHO HAD NOT RECEIVED IT.

Group	Total cases	Pneumonia cases	Per cent
Vaccine	307	10	3.3
No vaccine	297	6	2.0
Total	604	16	2.6

Table II shows that the "apparently poor" results of giving vaccine occurred chiefly among men. We feel that the result is not significant as only eight cases of pneumonia were involved.

We measured the "vaccine" and "no vaccine" groups separately for the succeeding tables. As there was no difference, we combined the two groups to gain size for the analysis with respect to age, past history of pneumonia and weight of patient.

TABLE II. INCIDENCE OF POSTOPERATIVE PNEUMONIA ACCORDING TO SEX OF PATIENT.

Group	Total cases	Pneumonia cases	Per cent
MEN			
Vaccine	173	6	3.5
No vaccine	161	2	1.2
Total	334	8	2.4
WOMEN			
Vaccine	134	4	3.0
No vaccine	136	4	2.9
Total	270	8	3.0

Only one case of pneumonia occurred among 224 patients less than fifty years of age, an incidence of 0.45 per cent. This case of pneumonia occurred in a patient who was forty-nine years old. Fifteen cases occurred among 380 patients fifty years of age and older, an incidence of 3.9 per cent. This strongly suggests that age is a large factor in the incidence of frank postoperative pneumonia.

A past history of pneumonia was given by eighty-four patients, one of whom contracted pneumonia postoperatively, an incidence of 1.2 per cent. Five hundred and twenty patients gave no past history of pneumonia; fifteen of these contracted pneumonia, an incidence of 2.9 per cent. This suggests that a history of pneumonia does not increase the risk of postoperative pneumonia.

TABLE III. INCIDENCE OF POSTOPERATIVE PNEUMONIA ACCORDING TO WEIGHT OF PATIENT.

Weight group, lbs.	Total cases	Pneumonia cases	Per cent
Less than 100	17	0	0.0
100-109	39	2	5.1
110-119	65	1	1.5
120-129	87	1	1.1
130-139	93	2	2.2
140-149	82	3	3.7
150-159	63	1	1.6
160-169	46	1	2.2
170-179	42	2	4.8
180-189	35	2	5.7
190-199	12	1	8.3
200 and more	23	0	0.0
Total	604	16	2.6

We studied the influence of the weight factor in postoperative pneumonia. Table 3 shows that the patients with higher weights do tend to have slightly higher incidence of pneumonia. However, correlation of age and weight shows that the older age groups are heavier than the younger groups. It would not seem that weight is as great a factor in the incidence of postoperative pneumonia as age.

An analysis of the cases on a time basis revealed two clusters of cases. One centered in October, 1937, and the other to a lesser degree from November, 1938, through February, 1939. We could find no correlation of the cases with personnel either pre-operatively, in the operating room, or postoperatively. Consecutive cases occurred in different wings of the hospital. No common source of the epidemics could be determined except that infections of the respiratory tract were unusually common at the time.

Conclusions

1. Respiratory vaccine administered pre-operatively under the conditions outlined and during the period in which two epidemics occurred did

not seem to reduce the incidence of frank postoperative pneumonia. In consideration of the results obtained by Rosenow and Heilman in the prevention of infection of the respiratory tract in persons not operated on and in animals, with the same vaccines as used in this study, several factors for consideration arise. The period of inoculation before operation may have been too short. Pneumonia developed in a very small number of cases. A negative report of this type does not deny the value of vaccine in the preventive treatment of infections of the upper part of the respiratory tract. Whether or not vaccine affected the severity of the pneumonia is difficult to ascertain.

2. Sex and weight are only slightly, if at all, associated with the incidence of postoperative pneumonia.

3. A history of pneumonia does not appear to increase the risk of postoperative pneumonia.

4. Age has a bearing on the postoperative incidence of pneumonia.

5. The cases occurred in groups, simulating an epidemic pattern. No evidence concerning the mechanism or source of the epidemic could be obtained.

The study strongly suggests that postoperative pneumonia may be seasonal. A careful study prolonged over a period of years might reveal the epidemic character more clearly and point out obscurely related factors. The data at hand do not in any sense deny the value of vaccine in the preventive treatment of infections of the upper part of the respiratory tract; they concern themselves only with the development of frank pneumonia after operation.

BURBOT LIVER OIL IN THE TREATMENT OF VARIOUS DERMATOSES*

JOHN F. WILSON, M.D.

Philadelphia, Pennsylvania

SINCE the work of Löhr[3,4] many investigators have studied the healing effect of cod liver oil. Its action is unknown but is thought to be related to the presence of vitamins A and D. The oil of the fresh water fish, the burbot (Lota maculota) has a high content of vitamins A and D.[1,2,5,6,7] This fish is found in the United States, especially in the Great Lakes and in the Lake of the Woods.[7] As the potency of vitamins in Burbot Liver Oil (N.N.R.) is at least seven times as great as the standard U.S.P. cod liver oil, it was decided to use this oil in the treatment of various dermatoses.

An ointment† was used containing 80 per cent of burbot liver oil. This concentration of fish liver oil is greater than that of the average cod liver oil ointment. It was used in the treatment of varicose ulcers, echthyma vulgaris, indolent ulcers following surgical procedures and psoriasis.

Varicose Ulcers

Because of the widely variable factors in the course of varicose ulcers, i.e. circulatory status and the local conditions of the tissue, making each case an individual problem, it was decided that a small number of carefully observed cases would be of more value than a large number of cases seen at infrequent intervals. Therefore, ten patients were admitted to the hospital, placed at rest in bed, the affected extremity elevated and the ointment applied to the lesion.

*From the Division of Dermatology, University of Minnesota, H. E. Michelson, M.D., Director, and the Dermatology Service of the Minneapolis General Hospital, S. E. Sweitzer, M.D., Chief.

†The ointment was supplied by the Burbot Liver Products Company, Baudette, Minnesota.

The improvement in each of these ulcers was carefully measured and the patients remained in bed until the ulcers healed. An attempt was made to plot a graph to show the progress of healing, but even with such standard conditions the individual differences were so great that each ulcer was a separate problem.

These patients ranged in age from fifty to seventy-one years and had suffered from recurrent stasis ulcers for ten to forty-seven years. They had been treated by various measures in the Out Patient Departments of the Minneapolis General Hospital and the University of Minnesota Hospitals for a period of at least four months but had not improved.

In view of the great individual differences in these cases it is difficult to evaluate accurately the results of therapy but it can be said that all of the patients improved rapidly with the use of this ointment.

Several of these patients showed remarkable progress.

Case 1.—B. W., aged fifty, a Chinese man, suffered from an eruption of the lower legs for ten years. During this time the skin of the left leg was ulcerated at various times and in spite of treatment two large ulcers had been present for five years. He was admitted to the Dermatology Service of the Minneapolis General Hospital on November 15, 1939.

On the left leg just above the ankle were two large ulcers. The upper one on the external surface of the leg was 9x6.5 cm. The lower ulcer was just above the medial side of the ankle and was 8x5.5 cm. The circumference of the leg just above the ankle was 20.3 cm. The depth of each of these ulcers was about 0.4 cm.

These ulcers had healed forty-seven days after the ointment was applied to the lesions.

Case 2.—G. P., aged sixty-three, a white man, was admitted to the Dermatology Service of the University of Minnesota Hospitals with varicose ulcers just above the medial aspect of both ankles which had been present for twenty years. He had been treated for several months in the Out Patient Department but the lesions did not heal.

The ulcer on the left leg was 3.3x3.7 cm. and that on the right leg, 3.3x3.8 cm. Burbot liver oil ointment was applied on February 3, 1940. On February 16, the ulcer of the left leg was completely healed and on February 27, both ulcers had healed.

The smallest of the ulcers treated were those described in the second case. The largest ulcer in the series was 10x5.5 cm. The average time of healing of these ulcers was thirty-eight and one-half days.

In addition twenty-three cases of varicose ulcer were treated with the ointment in the Out Patient Department.‡ An accurate evaluation of therapy is difficult under these conditions and other measures were used to improve the circulation, but all of these patients improved while using the ointment.

As is found commonly in the treatment of varicose ulcers some of the patients suffered an exacerbation of the dermatitis at the border of the ulcer where the ointment came in contact with the skin. This, however, quickly healed when the application was limited to the ulcerated area. Four of the thirty-three patients developed this dermatitis.

‡Nineteen of these patients were treated in the Surgery Out-Patient Department of the Minneapolis General Hospital, Arnold Zierold, M.D., Chief.

Other Dermatoses

Other dermatoses were treated with this ointment. Six patients with severe echthyma vulgaris of the lower extremities were admitted to the hospital and treated, and one patient with this condition received treatment in the Out Patient Department. All of these ulcers healed rapidly.

Four patients with psoriasis were treated. Two of these improved but later relapsed.

The ointment was also used to stimulate healing in three patients with ulcers following surgical procedures. These ulcers had been slow in healing but following the application of the ointment improvement was rapid and they healed quickly.

Summary

Forty-seven patients with various conditions of the skin were treated with an ointment containing 80 per cent of burbot liver oil.

Satisfactory results were obtained in the treatment of ulcers of the skin.

COLOCENTESIS—A GLIMPSE OF THE SURGICAL PAST*

COLIN D. L. CROMAR, M.B., Ch.B., F.R.C.S. (Ed.) and CHARLES W. MAYO, M.D.
Rochester, Minnesota

COLOCENTESIS, or deliberate puncture of the colon, is a procedure frequently employed in veterinary surgery to relieve cattle suffering from "sweet clover bloat," a form of tympanitic distention engendered by overindulgence in rich vegetable food. Animals in this condition are so inflated with gas, generated by fermentation occurring within the alimentary canal, that they become unable to stand, topple over and lie helpless on the ground, to die if prompt aid is not at hand. In these circumstances professional veterinarians recommend the insertion of a trocar through the gap between the last rib and the ilium on the left side to allow the gas to escape, but the practical farmer often achieves the same end by performing the operation with no more elaborate instrument than his pocketknife. In either case, the result is dramatic; gas issues from the wound in large quantities, the distended abdomen wilts and slowly returns to normal proportions and the animal is able to rise to its feet and resume its usual activities as if nothing untoward had happened. There are no unwelcome after-effects and cases have been recorded where particularly gluttonous calves have been punctured as many as twelve or fourteen times without mishap.

An onlooker could not fail to be impressed by this spectacular sequence of events wherein a seemingly moribund animal is restored to its pristine health, in a matter of seconds, by a relatively simple procedure, and it is not surprising that Clifford Allbutt[1] should have retained vivid memories of it from boyhood days spent in the country, and in later years have come to consider the possibility of employing a similar method for the relief of human suffering. The opportunity arose in 1869 when he was called in consultation by his colleague, Mr. Bradley, in the case of a laborer who had been admitted to the Leeds Infirmary as suffering from "obstruction of the bowels." His examination revealed that, although the bowel symptoms were the more prominent, they were caused by a reflex paralysis secondary to bilateral lobar pneumonia. The customary therapeutic measures, subcutaneous injections of morphine, and large enemas both with, and without, turpentine and castor oil had failed to give relief. The distended abdomen caused intense anguish, the extremities were cold, the pulse was small and quick, and the expression anxious. No feces had passed from the bowel for at least five days and no flatus for two.

Allbutt prescribed an injection of a quart or more of warm gruel to be administered slowly through a long tube and followed by an injection of half a pint of warm olive oil, in the hope that the oil might rise through the gruel and reach the obstruction. Belladonna liniment was also to be applied externally to the abdomen and the injections of morphine were to be continued. Although the liniment did have some effect in modifying the general discomfort, the injection of more than three pints of fluid was followed by the discharge of neither feces nor flatus. The patient spent a wretched night and the next morning his abdomen was even more distended and he hiccoughed continually.

"The previous evening," wrote Allbutt, "I had been much tempted to puncture the abdomen with a fine trocar, and in the morning the desire strongly returned." It was in this state of mind that he encountered the celebrated surgeon Teale who was also making rounds in the hospital that day. Laying the facts of the case before his colleague he asked him if he would care to perform the operation. Mr. Teale willingly consented and, producing a fine Weiss trocar from his pocket, he plunged it straightway in the distended transverse colon. A hissing sound heralded the escape of a vast quantity of malodorous gas, and a second puncture, this time in the descending colon, completed the deflation of the abdomen. The patient expressed great relief and thanked his benefactors warmly. His face grew calm and he breathed comparatively easily and soon fell into a quiet sleep. Aided by injections of morphine and soothing poultices, he passed a comfortable night and awakened refreshed on the following day. To his great delight he found that his bowels had regained their activity and he was able to pass large quantities of flatus and abundant stools. It is regrettable that in this case the pul-

*From the Mayo Foundation (Cromar, Fellow in Surgery) and the Division of Surgery, The Mayo Clinic, Rochester, Minnesota (Mayo). Submitted for publication October 1, 1940.

monary consolidation spread and caused the death of the patient two days later, but it is of outstanding interest that postmortem examination of the cadaver revealed no trace of peritonitis and no sign of gas in the peritoneal cavity, and most significant that the sites of puncture could not be detected except on the outside of the body.

The publication of this case was followed shortly by an article by Dr. James Davey[16] of Bristol which revealed that at his suggestion Mr. Salmon of Thornbury had performed a similar operation in the previous year (1868) on a girl of nine years suffering from tuberculous peritonitis. As the disease approached its terminal phase the child became progressively emaciated and her abdomen was hugely distended. Palliative measures were of no avail, and realizing the desperate nature of the case Davey decided that it would be wisest to puncture the abdomen to relieve the distention. "The enormous quantity of gas or wind occupying the peritoneal sac, or it might be, the intestines, being nothing more or less than a foreign body, or at any rate, a product of abnormal action in the parts concerned, should be evacuated." This was the proposition he made to Mr. Salmon as they drove home together after the consultation. Mr. Salmon was not convinced, and so to support his contention Davey developed his argument to a further stage by maintaining that if instead of air they felt assured that there was fluid or water (ascites) within the abdomen an operation would surely be held to be imperative. This Mr. Salmon could not refute, and on the following day he performed the operation. The abdomen was punctured letting out an immense quantity of gas, which continued to discharge at intervals until the patient's death two weeks later. Mr. Salmon commented that "the operation gave great relief, and tended much to mitigate her suffering, previously to which the difficulty of breathing had been most distressing." Necropsy showed typical tuberculous peritonitis with deposits of lymph, adhesions, purulent effusion, and so forth. In addition there were three ulcers of the bowel, one of which had perforated, allowing feces to escape into the peritoneal cavity. This perforation, however, was nowhere near the site of the puncture.

Another protagonist of colocentesis was Dr. Fonssagrives[22] of Toulouse. In the *Medical Press and Circular* of April 7, 1869, it is recorded that by his advice intestinal puncture had been practiced "as a last resource" on two patients suffering from tympanites. The abdomen of the first of these was so swollen with gas that the patient was deeply cyanosed and on the brink of suffocation. An exploring trocar was inserted into the most distended part of the lower umbilical region and the gas escaped violently. The next day, as the distention had returned, two fresh punctures were made in different places and gave so much relief that the life of the patient was prolonged for four days. In the second case, six successive punctures restored to the patient the power of passing flatus naturally and thus effected a complete cure.

The following year, the operation was reported by Mr. Hancocke Wathen[45] of Fishguard. On reading of Allbutt's case he had decided to try the procedure himself in the first suitable case which came his way. His patient, a woman of twenty-nine years, was suffering from a fulminating acute peritonitis. She presented all the appearances of severe shock and her abdomen grew large and tympanitic. The usual palliative procedures produced free fecal evacuations but gave no relief from the distention. The patient rapidly became exhausted, and three days after the onset of the disease she expressed her willingness to submit to colocentesis. Using a No. 1 hydrocele trocar, Mr. Wathen punctured the transverse, the descending and lastly the ascending colon. A candle held near the scene of operation was extinguished by the force of gas escaping from the first two punctures. Great relief was expressed by the patient but her general condition was unsupportable and she gradually grew weaker and died the next day. Permission to hold a postmortem examination was not obtained.

Mr. Wathen[46] also referred to a case which had occurred in the practice of his friend, Staff-surgeon J. R. Thomas,[43] on the West Coast of Africa. The patient, an American, was smitten with chronic dysentery accompanied by a gradually increasing tympanites which eventually became intolerable and made him beg for relief by any means possible. Puncture of the transverse and ascending colon was practiced "with the best result" but unfortunately a few days later the patient, who had been up and about, "went in for a heavy debauch" and suffered a relapse which terminated fatally.

In October, 1871, Allbutt[2] announced that since

his first venture he had himself performed colocentesis four times, "deeming it as venial an operation for a physician as the injection of morphia." He had used the Weiss No. 1 exploring trocar, which he now carried in his bag for that purpose, on three occasions, and his morphine needle twice. He regarded the trocar as being as innocuous as the needle and believed that it possessed the advantage of allowing the more rapid escape of gas. His individual cases are interesting.

In the first case the patient, an old man and a stranger to Leeds, had been taken ill suddenly in a second-rate lodging house of that city. Allbutt, summoned hastily during the small hours of the night, found him suffering from pneumonia, with severe orthopnea, an intermittent laboring pulse and a dusky complexion. His chief distress was the enormous distention of his bowel which pressed on his diaphragm and embarrassed his elderly and degenerate heart. The colon was punctured twice; gas rushed from the cannula with great violence and in a few minutes, revived by a dose of ether in hot brandy and water, he was able to lie down in peace. Some weeks later Allbutt was gratified to receive a letter posted from a distant village in Yorkshire in which the patient enclosed his fee and affirmed that his life had been saved by this timely intervention.

Another case of heart disease in which sudden and intense tympanites threatened to kill the patient was treated successfully by puncture of the colon, the patient's life being prolonged for weeks or months by the operation. Temporary relief was afforded to two patients with paralytic distention of the bowel developing in the course of febrile illnesses but both died subsequently from the severity of the causal disease.

The publication of these cases aroused a lively interest in colocentesis and the literature of the period contains frequent references to this type of procedure. It became apparent moreover that it was not altogether such a novelty as had been supposed. Dr. Symes Saunders[37] not only provided this evidence but was able to endow the operation with a respectable historical background. He declared that the first man to use the trocar successfully in the treatment of tympanites was François de Paule Combalusier,[40] who is said to have performed the operation as early as 1754. Saunders suggested that the procedure may have evolved from the practice of "needling" the bowel during the operation for hernia, as advocated by Ambroise Paré, Corneille de Soolingen, and Pierre Dionis, and he drew attention to a passage in Heister's[27] "Surgery," where it is recommended that in pneumatocele or "hernia flatulenta," if ordinary remedies have failed, the scrotum should be perforated with a trocar, "which will demonstrate whether it was wind or water."

By the beginning of the nineteenth century the operation of colocentesis had achieved recognition by the standard textbooks of the day. Benjamin Bell,[5] observing that the operative danger was slight in lower animals, advised that the intestine should be punctured in tympanites, and Callisen,[10] in his "System of Surgery" (1813), approved its use as a palliative in this condition. Charles Bell,[6] on the other hand, did not favor the operation, and said so bluntly. Zang,[49] giving precise instructions as to operative details, recommended that a long trocar should be introduced to a depth of 4 or 5 inches at the midpoint of a line extending from the foremost extremity of the second false rib on the left to the anterior superior iliac spine on the same side. At this site he believed it was possible to penetrate the descending colon without injury to its mesentery. He considered the operation to involve no more danger than simple puncture because, after withdrawal of the cannula, the wound in the intestine did not exceed half a line in extent. Roche,[35] writing in 1835, stated that, as a last resort, the abdominal wall may be punctured, and although he regarded the operation as dangerous he appreciated that it had been practiced a number of times with success. The 1852 edition of Chelius's[13] "Surgery" advocated paracentesis in distention of the alimentary canal when the ailment is idiopathic and not a symptom of other disease.

Although these observations are of great interest, their value is chiefly historical, for they contain no record of the cases in which the procedure was actually employed. The earliest case of which we have accurate details was published by Sir Henry Cooper[14] of Hull in 1857. Calling to see a woman of thirty-four years with complete intestinal obstruction caused by an inflammatory process, which occluded the ascending colon, he elected to puncture the cecum. The needle was left in place to allow the lymph to seal off its track and so prevent possible spread of

infection. The escape of flatus was followed by fluid feces and at the end of three days the needle was withdrawn and replaced by a gutta-percha tube which served to keep the wound open. The feces were kept soft by the exhibition of saline laxatives, and thirteen months later the patient was reported as being alive and well. She still used the puncture wound as a cecal outlet, no feces having passed from the anus since the operation.

The peculiar dietetic habits of the South Americans are reflected in a report by Olivieri[32] in 1861 of a series of cases, which savors almost of veterinary practice. He performed colocentesis in twenty cases in which the symptoms were those of abdominal distention caused by overloading the stomach with half-cooked vegetable food washed down with badly fermented liquor prepared from maize. Eight of the patients recovered in three weeks but the remainder died because treatment had been delayed until too late.

The first mention of the operation in the North American literature is to be found in Dr. Gross's[26] well-known "System of Surgery" published in 1866. Here, he described the case of a man with a perforating scirrhus of the sigmoid colon. The prognosis was hopeless from the start but great symptomatic relief was conferred by colocentesis and the patient's life was prolonged for some three weeks. The author was enthusiastic in his recommendation of the operation.

Reports published in France in 1871 state that Boinet[8] had frequently punctured the bowel as often as five or six times in one month without harm to the patient. The secret of success, he said, was to use a fine needle. Tarnier[42] reported several cases of internal strangulation which he had treated by this means. Desnos and Chalvet[18] successfully relieved a patient of hysterical tympanites by aspirating the distended bowel and, despite the fact that feces were withdrawn, no ill effects ensued. Puncture of the bowel was also tried for the relief of strangulated hernia and successful examples were recorded by Duplony,[21] Dugue[20] and Giraldes.[23] The greatest significance of this adaptation, however, lies in certain experimental observations which evolved from it. Dolbeau[19] reduced a strangulated hernia by tapping the trapped bowel, the first puncture yielding liquid feces and the second, reddish fluid. The patient died next day of heart disease and an opportunity arose to examine the loop of the bowel which had been punctured. It looked perfectly healthy and the puncture wounds could not be discovered. Even when it had been inflated with air under pressure it remained impervious and not one bubble of air escaped. In a thesis by Autun,[4] he described several experiments on rabbits in which he pierced the intestines in various directions without any ill effects to the animals.

The popularity of colocentesis grew rapidly among surgeons throughout the civilized world and its results were acclaimed with enthusiasm. Sir Howard Marsh[30] reported "great relief" and subsequent recovery; Lawson Tait[41] cited "numerous punctures for days on end" without adverse effect. Godfrey[24] of Chicago claimed to have cured a case of suspected intussusception by puncturing the abdomen in both iliac fossæ and drawing off a pint of feculent fluid. Wentscher[47] recorded cure of ileus by puncturing the colon in the left nipple line above the navel. Martyn[31] of Bristol overcame an obstruction in the sigmoid by repeatedly tapping the descending colon with a trocar.

McGown[28] of Glasgow pierced the transverse colon of a patient in the throes of acute obstruction from an intussuscepting lesion in the left portion of the colon. Here are his words: "But now comes the wonderful part of the case. Three hours after the operation the patient had a very copious discharge from the bowels of dark clayish liquid feces, followed by a second an hour after the first. Seven hours after the operation a large quantity of gas was passed PER ANUM, and the next morning the abdomen was quite flat and the distention completely gone. The kidneys now began to act vigorously. The ordinary chamber utensil was filled three times in sixteen hours, and at the end of three days all the edema of the limbs had disappeared. The heart's action was now greatly increased; the pulse rose from 48 to 70 per minute. The patient has improved every day since the operation and is gaining flesh rapidly. . . . I look upon this case," he continued, "as one of the triumphs of surgery; and should a similar case present itself to any of my medical brethren, I hope they will not hesitate to give their patient immediate relief and the chance of complete recovery by the operation of Colopuncture."

Several authors claimed to have attacked the

small intestine with no less success. Thus Demons[17] of Bordeaux cited the case of a woman with a pelvic abscess and symptoms of intestinal obstruction which he treated by multiple punctures on six successive days until finally the abscess localized in the left fornix and it became possible to drain it by surgical means which also gave relief of the obstructive symptoms. In a case of obstruction occurring in the ileocecal region, Perry[34] recorded that he punctured the ileum and left the trocar in place for three to four hours until a large quantity of gas and a quart of fecal matter had been evacuated. The nausea and vomiting were reduced "as if by magic" and the distention was much relieved. Bell[7] of Edinburgh, commenting on a case of volvulus, in which the symptoms of abdominal distention had been mitigated temporarily by puncture, asked, "can we relieve this distention easily, painlessly and safely?" "I believe we can," he answered, "in the simplest manner, by tapping the bowel with a fine exploring needle." Rosenbach,[36] too, recognized the value of puncture as a palliative procedure and recorded four cases in which he had performed it successfully.

Colocentesis as a means of reducing distention preliminary to major abdominal operations has been employed on several occasions and cases reported by Pearse,[33] Cutler and Homans,[15] Sheen[38] and Frank L. Smith[39] indicate that in this capacity it met with a fair degree of success. It is interesting to note that in many of these cases the bowel had been subjected to the most drastic forms of therapeutic abuse before the puncture was finally performed. In Smith's case, for example, the patient had been treated with Clutterbuck's elaterium, pil. podophyllin co., croton oil and massive doses of belladonna by mouth, and mustard water, the long tube and even the pole of a galvanic machine had been introduced into the rectum in an endeavor to overcome the obstruction without resorting to operation.

As an aid to pre-operative diagnosis, aspiration of the colon was recommended by Maclaren[29] of Carlisle. "In the aspirator," he wrote, "we have an instrument which will determine whether any given portion of the colon contains liquid or not. If it does it is of necessity above the seat of stricture." Amussat[3] suggested that by puncturing the bowel and thus reducing the distention it might be possible to feel an otherwise impalpable lesion but he added that in his experience he had never had occasion to resort to this expedient.

The most ingenious modification of colocentesis is that described by Chadwick[11,12] of Boston. He had tapped the colon of a woman of thirty-two years in whom peritonitis had developed following ovariotomy, and the release of abdominal distention had given much relief at the time although her poor general condition arising from a habit of "free indulgence in spirituous liquors" had militated against a successful recovery. In reviewing this case he conceived the idea that it might be possible to inject some stimulant into the intestine after the gas had escaped. He believed that by this means the patient's strength might be sustained at a time when nothing could be kept in the stomach and absorption by the rectum was too slow to satisfy the needs of the body. He also wondered whether it might be possible to stimulate peristalsis by the injection of suitable liquids into the lumen of the bowel. The test was carried out on a young woman in whom peritonitis and ileus had developed following a complicated labor. When flatulent distention became so great as to impede her respiration, the smallest trocar of Potain's aspirator was introduced through the abdominal wall into what appeared to be the transverse colon or sigmoid flexure. A rubber tube attached to the cannula led by its other extremity to a basin of water, so that the escape of gas could be noted by the steady rise of bubbles in the water.

After a large amount of flatus had escaped, the tube was pinched, a syringe was connected to its end, and an attempt was made to inject beef tea into the intestine. The cannula became plugged by little shreds of meat which were floating in the liquid and the injection was thereby rendered impossible. As it would have taken considerable time to strain the fluid and this would have added to the mental agitation of the patient, a solution was made up of "very choice rye whiskey" in three parts of water and this was injected instead. The injection was successful, but the very first drops of the fluid gave the woman so intense colic—referred to a spot below the point of the injection—that it was stopped at once, for fear that the intestinal wall had dropped off the end of the cannula and that the whiskey had been allowed to enter the peritoneal cavity. As the pain soon subsided, the injection was resumed, with similar effect, ex-

cept that the pain was less acute and produced a sensation described as a "burning." It was not deemed justifiable to subject the patient to further suffering, and accordingly the experiment was abandoned after it had been definitely established that the cannula was still in the intestinal lumen, by allowing more gas to pass off before it was withdrawn.

The woman continued to complain of intermittent lancinating pains running down to the groin and these were clearly the result of peristaltic action. As this excessive peristalsis seemed undesirable in view of the inflamed condition of the intestines, a quarter of a grain of morphine was administered hypodermically. Ten minutes later the patient complained "that something was about to pass from the bowels." Digital examination revealed the presence of two large scybala in the rectum which had previously been empty, although not even flatus had escaped during the previous twelve hours. She died of septicemia two days later and no necropsy was allowed. At the conclusion of his paper Chadwick stated: "as a means of exciting peristaltic action, my procedure was eminently successful. The extreme sensitiveness of the intestinal mucous membrane to the contact of an alcoholic fluid so dilute as not to produce any astringent sensation in the mouth or rectum is worthy of note."

In a lecture to the students of Guy's Hospital on the subject of intestinal obstruction, Goodhart[25] drew attention to the danger of fecal contamination of the peritoneal cavity as a result of colocentesis, stating that he had seen a case in which fecal matter had escaped from the cannula, no relief had followed and the patient had died. We have been unable to find a case of this type anywhere in the literature but this may be explained on the basis of the infrequency with which failures find their way into print. At the time of publication Goodhart's warning did not pass unchallenged but was heartily contested by Mr. Alfred Sheen[38] of Cardiff. "I certainly cannot see the force of Dr. Goodhart's argument," he said. "I would submit, that as the gas escapes from the distended intestine the latter contracts and the arrangement of the muscular fibres of its coat would surely prevent the escape of its contents into the abdomen where such a small opening is made." This hypothesis is borne out by the experimental evidence which we have already quoted, and also by observations made on material obtained at necropsy. It is further confirmed by the statement of Maclaren who attended the postmortem examination of a case in which the aspirator needle had been pushed into various portions of the bowel during the six hours preceding death and was unable to find any traces of its use. Certain writers have described cases in which peritonitis followed attempts to aspirate the contents of a strangulated hernia, but it can be readily appreciated that in this condition the bowel may be so devitalized as to be incapable of sealing off the wound made by the needle.

It is true that complications directly attributable to puncture for tympanites have been reported, but in the absence of strangulation—these have been few in number and relatively insignificant in effect. Broadbent[9] punctured the small intestine in obstruction caused by adhesions to an ovarian cyst. As the gas was escaping, the patient coughed and the intestine became displaced. The needle was rapidly withdrawn but a small amount of subcutaneous emphysema developed. This subsided completely in the course of time and no harm resulted. Worthington[48] described a case in which the transverse colon had been punctured; air escaped, followed by fecal fluid; the cannula then became blocked and had to be cleared with silver wire. The patient's temperature rose to 100.2° F. that night but had dropped to 99° F. by the next morning. A little local tenderness was experienced at the site of the puncture but it dispersed in two or three days. Wagstaffe[44] recorded that he successfully relieved an obstruction in a somewhat irresponsible young Irish physician by tapping his bowel. Four days later this gentleman rather imprudently elected to rise from his bed of sickness and go out for an hour's walk. In consequence some local peritoneal irritation developed but this also cleared up satisfactorily in a few days.

The weight of evidence therefore suggests that colocentesis is a relatively safe procedure and that, in addition to the ability of the bowel to seal the puncture rapidly, the peritoneum is well equipped to deal with any leakage which may occur. Certain precautions however have been suggested in order to make the operation even safer. The importance of tapping a coil of bowel which contains gas rather than feces has been stressed by Broadbent who has also drawn attention to the danger of tearing the bowel if care

is not taken to insert the needle at the point of greatest convexity of the distended loop. Should the needle become blocked, it is wiser to clear it by injecting air rather than by suction which might cause damage to the mucosa of the opposite side of the lumen of the bowel by drawing it against the sharp point of the needle. To prevent the escape of fecal contents from the cannula while it is being withdrawn, Wagstaffe suggested that a finger should be placed over the end of it to exclude the influence of atmospheric pressure. Perhaps this danger is more theoretical than real, for, in several of the reported cases, fecal material was withdrawn through the cannula and no complication ensued.

When, at the end of the last century, Lawson Tait demonstrated to the world that the abdominal cavity could be explored with relative impunity, intestinal obstruction became a major surgical emergency which demanded immediate laparotomy to enable the surgeon to see and cope with the actual cause of the obstruction. The older methods were discarded, and such remedies as O'Bierne's tube, Simon's procedure and a host of other examples of the ingenuity of a bygone generation were consigned unceremoniously to the scrapheap. With them went colocentesis, and condemned by common vote as "enterostomy performed in the dark," it thus slipped quietly out of the practice of surgery.

GUARDING THE SUPPLY OF HELIUM

The U. S. government's helium plant in Texas is the world's sole producer of helium. About 15 per cent of the output of the plant is sold for medical, scientific and commercial use, the other 85 per cent of the output being supplied directly to the government. At the current rate of production this plant will produce by the end of the fiscal year about 14,000,000 cubic feet of helium. The plant has produced more than 110,000,000 cubic feet of helium since it began operations about twelve years ago. There are proposals now in Congress to increase both the well and the plant capacity. Measures are being taken to insure that no interruption in operation shall occur. Dr. R. R. Sayers, director of the Bureau of Mines, reported to the Secretary of the Interior that steel guard towers are being constructed at strategic points. A tower is being erected also in the gas field from which a general view of the government's helium properties can be obtained.—*Jour. A.M.A.*, May 17, 1941.

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL
Frank C. Andrus, Pathologist

The case is that of twenty-seven-year-old woman who was admitted to the hospital on April 15, 1941, and expired seven days later. Her present illness began on April 6, 1941, when she noted a sore throat. Her temperature was 102 degrees. She went to bed and remained there. On April 9, 1941, a nose and throat culture was taken which was negative for diphtheria bacilli. On April 10 the patient developed marked laryngitis, and on April 11, she coughed up several small pieces of what appeared to be a membrane. During this time, the patient's oral temperature had been ranging from 102 to 104 degrees and her throat was extremely sore. On April 12 she was admitted to a private hospital. Nose and throat cultures were repeated and were again negative. On April 15 the cultures of the nose and throat were positive for the first time and she was transferred here. Past history was negative. She was married and had three children who were living and well. Her youngest child was admitted to the hospital at the same time as the mother, also suffering from a sore throat. The cultures from the child's throat yielded diphtheria bacilli.

Physical examination on admission revealed an oral temperature of 101 degrees, a pulse rate of 115 per minute, and respirations of 24 per minute. The patient was well developed and rather obese. She did not appear to have any respiratory distress. There was a rather marked facial flush. Examination of the eyes, ears and nose revealed no abnormalities. Examination of the throat revealed a thick, dirty, greyish membrane covering the tonsils, uvula, and the pharynx. A slight amount of bleeding was noted at the margins of the membrane. There was moderate enlargement of the anterior and posterior cervical lymph nodes. The lungs were clear to percussion and auscultation. The heart showed a normal sinus rhythm and no murmurs were heard. The abdomen and extremities were negative. She was having fairly marked difficulty in speaking at this time and the impression of the staff was that she was suffering from pharyngeal and laryngeal diphtheria.

The hemoglobin was 92 per cent with a leukocyte count of 15,000 of which 83 per cent were polymorphonuclears, 14 per cent lymphocytes, and 4 per cent monocytes. Examination of the urine revealed the specific gravity to be 1.029. It contained four plus albumin, occasional granular casts, many red cells (menstrual blood), and occasional white cells in a non-cathetrized specimen. A nose and throat culture was negative. A guinea pig was inoculated from a culture and while it became sick, it recovered. On the day of admission, the patient was given 40,000 units of diphtheria antitoxin intramuscularly and 40,000 units intravenously. On the evening of the same day, she coughed up a cast of the trachea, larynx, and a good portion of the bronchial tree. Diphtheria bacilli were found on direct smear of this membrane. On April 16, at approximately 12:15 a.m., the patient had a severe coughing spell and coughed up a thick piece of membrane measuring 2 x 1 inches. Again, following a severe coughing spell, at 4 a.m. on April 16 she coughed up another piece of membrane measuring 1 x 1 inches. Later in the morning of April 16, the patient appeared to be much better and stated that her throat was less sore. Her temperature had fallen to 100 degrees.

On April 17 her temperature was 105.4 degrees by mouth. She suddenly became very listless, her pulse very thready and 140 per minute. There was no respiratory distress but her lips and fingernails were cyanotic. The heart tones were barely audible, but there was no irregularity. The blood pressure was 80/60. Examination of the chest revealed coarse rhonchi throughout both lungs. There were, however, no areas of dullness. Numerous petechiæ appeared over the right flank and upper chest. The impression at this time was that the patient now had a diphtheritic myocarditis. On April 18 the patient's temperature had fallen to 102 degrees and her pulse rate to 120 per minute. She appeared to be much better. An x-ray film of the chest revealed a complete consolidation of the right upper lobe. There appeared to be some atelectasis along with the consolidation. There was also some increased density in the para-hilar region on the right side and in the lower half of the left lower lobe. A blood culture taken at this time was negative. On this day, April 18, the patient received a total of 660 c.c. of fluid but she had no output of urine. An effort was made to type the sputum but no pneumococci were found. The sputum was inoculated into a mouse but its peritoneal fluid was sterile at the end of seventeen hours. On April 18, she was given four grams of sodium sulfathiazole intravenously. This was followed by one gram intravenously four hours later. Her respirations were very rapid and shallow. She appeared to be quite comfortable; her color was good. The pulse was fairly strong but it was now markedly irregular. For the first time, a one plus pitting edema was noted over the tibial regions. The venous pressure was 15 cm. of citrate solution. Urinalysis now revealed the specific gravity to be 1.022. The urine contained four plus albumin and occasional red and white cells. The patient developed a pharyngeal paralysis. It was

thought that the edema and the irregular pulse were due to diphtheritic myocarditis. Because of the severe oliguria, it was considered necessary to give the patient additional fluids in spite of the probable heart failure. The sodium sulfathiazole therapy was discontinued because of the oliguria and the fact that no pneumococci could be isolated in the sputum or on mouse inoculation.

In the evening of April 18, an electrocardiogram revealed slight slurring of the QRS complexes in all three leads, a sinus tachycardia, and occasional ventricular extrasystoles. On April 19 the patient's temperature ranged between 100 and 101.5 degrees and her pulse between 110 and 120 per minute. She was given 2000 c.c. of 10 per cent glucose intravenously at a very slow rate and her total intake for this day was 2830 c.c. Her output, however, for the twenty-four-hour period was only 200 c.c. This urine had a specific gravity of 1.023, contained four plus albumin, and occasional red and white cells. The patient appeared extremely toxic and her respirations were gasping in character. The pulse was of a fairly good volume but was again noted to be irregular. Moderate edema was noted over both extremities and over the sacrum. Examination of the chest on this day revealed consolidation bilaterally. An electrocardiogram was repeated and revealed extra-systoles occurring as a pulsus trigeminus. The P-R interval varied between .14 and .16 seconds. Otherwise, there was no change from the previous tracing. The blood urea nitrogen was 103 mg. and the creatinine 5 mg. per cent. The carbon dioxide combining power was 38 volumes per cent. Blood pressure determinations during the day of April 19 were 96/60, 98/65, and 104/68. The patient's temperature was 100.4 degrees on April 20 and her condition appeared even more critical than previously. Her respirations were very rapid and shallow but she responded quite well. The cardiac decompensation did not appear to be any more severe. The petechiæ seemed to be disappearing. The pulse rate was now regular at 100 per minute and of good volume. She received 1000 c.c. of fluid intravenously during this twenty-four-hour period, this being her only intake. Her urinary output was 425 c.c. Examination of this urine revealed a specific gravity of 1.022, three plus albumin, many granular casts, 10 to 12 red cells, and numerous cellular casts. The question of acute glomerular nephritis was now raised. During the evening of April 20 she suddenly became very dyspneic and was given a BLB mask with 100 per cent oxygen. The dyspnea seemed to improve under this therapy. On April 21 very little change in her condition was noted. The heart tones were quite loud and there were occasional extrasystoles. No murmurs were heard. However, her pulse rate varied as much as 40 beats within a period of five minutes. Her fluid intake was 1000 c.c. intravenously and her output was 750 c.c. Examination of this urine revealed the same findings as before. Her blood urea nitrogen was now 81.6 mg. per cent. On the evening of April 21 her temperature became elevated to 103 degrees and her respirations to 56 per minute. The pulse rate was 120 per minute although it would vary considerably in rate within a few minutes. On the morning of April 22, the pulse rate seemed somewhat stronger although it was still quite irregular. The patient was very restless, cyanotic, and her respirations were 54 per minute. Her pulse gradually became weaker, her temperature became elevated to 106 degrees and she expired.

Clinical Diagnoses: Pharyngo-laryngo-trachea-bronchial diptheria, myocarditis, pneumonia, possible acute glomerulonephritis.

Anatomic Findings (Dr. Martin Buehler):

The body is that of a well developed and rather obese white woman. There are numerous small, scattered petechiæ over the lateral sides and the anterior surface of the chest, the upper arms, and the abdomen. The mouth contains a quantity of dried blood. There is a one-plus pitting edema of the ankles, the pre-tibial regions, and the sacrum. There is cyanosis of the fingernails and the lips.

The heart weighs 280 grams. The heart muscle shows cloudy swelling, the myocardium being pale and flabby. The valves of the heart are entirely normal. The coronary arteries are normal.

The right lung weighs 1220 grams and the left lung weighs 940 grams. There is a complete, red consolidation of the entire left lower lobe and the superior three-quarters of the upper lobe of the left lung. These portions of the lung are entirely airless and solid. A profuse bloody discharge is easily expressed from the cut surface. There is complete consolidation of the entire right upper and lower lobes and one-half of the right middle lobe. The bronchi are traced to their terminal branches and all are filled with bloody, frothy fluid. There is, however, no evidence of any membrane at this time.

The liver shows a minimal degree of chronic, passive congestion.

The right kidney weighs 240 grams and the left kidney weighs 220 grams. Both kidneys reveal cloudy swelling. The cortices and pyramids appear normal.

A hemorrhagic, pseudo-membrane is noted in the trachea and in the larynx. There are a few mediastinal and paratracheal enlarged lymphnodes.

Discussion

Dr. Frank C. Andrus: Microscopic study of the kidneys reveals only cloudy swelling and albuminous casts in the tubules. There is no visible glomerular change. The uremia is probably partly due to the fall in blood pressure.

The myocardium shows an acute, exudative, interstitial myocarditis. The trachea and larynx have the characteristic changes of diphtheria, part of the membrane being still present.

The lungs show a well-marked pneumonia of the type often seen due to streptococci. With all of the denuded surface of the trachea and bronchi, it is easy to postulate a portal of entry.

Anatomical Diagnoses: (1) Pharyngo-laryngo-tracheo-bronchial diphtheria; (2) Acute exudative myocarditis; (3) Myocardial failure, mild; (4) Pneumonia, probably streptococcic; (5) Cloudy swelling of liver, heart, and kidneys.

Dr. Edward L. Strem: From January 1, 1934, to the same month of 1941, there have been 161 cases of diphtheria of all types treated in this institution. In reviewing the records of these patients, it was found that the age distribution ranged from early infancy to late adult life (Chart I). Of the entire group, 45 per cent were children from eight months to fifteen years, and the remaining 55 per cent were individuals from fifteen to sixty-seven years.

TABLE I. THE DIFFERENT TYPES OF DIPHTHERIA ENCOUNTERED AND THEIR INCIDENCE

Type	*Number of Cases*
Pharyngeal	128
Laryngeal	14
Pharyngo-laryngeal	13
Naso-pharyngeal	3
Nasal	1
Naso-pharyngo-laryngeal	1
Diphtheritic balanitis	1
TOTAL	161

The most commonly encountered type of diphtheria was that involving the pharynx. Next in frequency were the laryngeal and pharyngo-laryngeal types. These three comprised 155 of the total number. Their incidence is shown in Table I.

There was a history of previous attack of diphtheria

TABLE II. COMPLICATIONS OBSERVED IN 161 CASES OF DIPHTHERIA

Complication	*Number of Instances*
Myocarditis	7
Pneumonia	7
Atelectasis of lung	2
Paralyses	2
Acute glomerulonephritis	2
Edema of lung	1
Edema of larynx	1
Cerebral damage from asphyxia	1
TOTAL	23

in two cases: one thirteen years before and the other five years. One of these had received antitoxin. Five patients had been actively immunized, one to three years prior to contraction of the disease.

Antitoxin was administered in all but two instances. Of twenty-eight patients with laryngeal involvement,

TABLE III. YEARLY INCIDENCE AND MORTALITY RATE OF DIPHTHERIA AT MINNEAPOLIS GENERAL HOSPITAL 1934 TO 1941

Year	Number of Cases	Deaths	Mortality Rate (Per Cent)
1934	59	4	6.7
1935	22	3	13.6
1936	45	7	15.5
1937	5	0	0
1938	8	2	25
1939	8	1	12.5
1940	14	3	21.4
TOTAL	161	20	12.4

fourteen required interference to combat asphyxia. This consisted of intubation in five, tracheotomy in eight, and bronchoscopic aspiration in one. Of these, there were seven deaths, six occurring in children under ten years of age.

Complications were encountered in 9 per cent. Myocarditis and pneumonia were by far the most frequent. Edema of the lung, of the larynx, and cerebral damage from asphyxia were the least commonly observed. Paralyses, acute glomerulonephritis, and atelectasis of the lung comprised the intermediate group. These complications are tabulated in order of frequency, Table II.

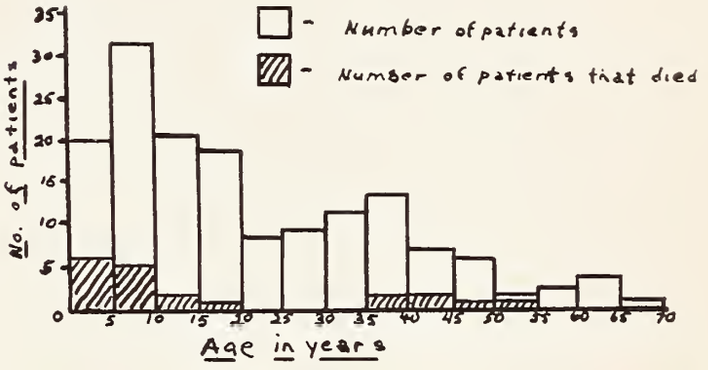

Chart 1. Age incidence and fatality of 161 cases of diphtheria.

The yearly mortality rate varied from zero to twenty-five per cent. For the entire period, the mortality rate was 12.4 per cent (Table III).

The twenty fatal cases showed laryngeal involvement in fourteen and pharyngeal in five. The remaining case was a diphtheritic balanitis. The greatest number of deaths occurred in the youngest age groups. This is represented by the shaded areas in Chart 1.

Dr. E. T. Bell: I have seen numerous cases of laryngeal diphtheria with negative throat cultures. Cultures were checked by expert laboratories and still came back negative. You simply have to go by the clinical impression and give antitoxin. If you wait for positive cultures, things happen as they have in this case. It is rather surprising to see such a large number of older people with diphtheria. It brings out well the point that diphtheria is by no means exclusively a disease of childhood.

Dr. A. V. Stoesser: I am sure that if you take a careful enough history in most of these cases, and if you go back into their history far enough, you will find that they have had a sore throat for some time. The difference between the cases we see today and those we saw some years back is that they are now not discovered soon enough. Physicians are not looking for diphtheria as they used to. A few years ago, if the doctor saw a patient with a sore throat, a culture was taken, usually by himself. I think that it is a mistake to permit nurses and orderlies to take nose and throat cultures. We must emphasize the importance of taking the cultures in the presence of sore throat whether it be in a child or in an older individual. Another thing that should be mentioned is the dosage of antitoxin to be administered. For some time, we made the mistake of giving too little antitoxin. Now we give adequate amounts. Some physicians believe that antitoxin in large doses is harmful, but I see no evidence of that. Any excess of antitoxin administered is merely excreted in the urine.

Dr. E. T. Bell: What per cent of the children in this community have been immunized to diphtheria?

Dr. A. V. Stoesser: I do not know the exact per centage but we have a very poor record here in comparison to some of the other large cities. There is no doubt but that when Schick tests are negative, that community is rid of diphtheria.

CAROTIDO-CAVERNOUS FISTULA*

KARL C. WOLD, M.D., and ROBERT W. HOLMEN, M.D.
Saint Paul, Minnesota

TRAUMATIC rupture of the internal carotid artery in its passage through the cavernous sinus is the most frequent anatomical cause of pulsating exophthalmos, according to Meyer and Sugar who have reviewed the entire literature to 1939 and found 786 cases of this rare condition. The next most frequent cause is a spontaneous fistula between these vessels, usually due to a generalized arteriosclerosis and less commonly to vascular syphilis, and found in an older age group. Other causes are vascular tumors of the orbit or surrounding tissues, simple aneurysms of the ophthalmic artery, arteriovenous fistula involving the internal carotid artery and the internal jugular vein at the entrance of the carotid canal, arteriovenous communications within the orbit, and absence of a large part of the orbital roof.[1]

The typical picture of pulsating exophthalmos due to carotido-cavernous fistula follows a head injury severe enough to cause a period of unconsciousness. Soon after recovering consciousness the patient becomes aware of a rushing noise in his head which is more marked when he is lying down or is in a stooped position. Double vision caused by paresis of one or more of the ocular muscles, usually including the lateral rectus, makes its appearance. Vision fails, and the eyeball bulges from its socket. Pulsation of the orbital contents may or may not be obvious. Edema of the conjunctiva is common. A swishing bruit, synchronous with the pulse beat, may be heard through the stethescope when placed over the orbit or temporal region and may be caused to disappear or to be modified by digital compression of the common carotid artery. Examination of the eye grounds reveals evidence of engorgement.

Treatment is necessary for visual, subjective, and cosmetic reasons. According to de Schweinitz 20 per cent of all cases terminate in blindness and no more than 11 per cent retain normal vision. Rest may result in clot formation and a spontaneous cure. Surgical treatment includes ligation of the internal or common carotid artery. Whether to ligate the internal carotid or the common carotid is apparently a moot question. But either ligation should be preceded by gradually increasing periods of digital compression of the common carotid artery until the patient is able to tolerate such compression for at least thirty minutes.[2]

The collateral circulation, after ligation of the common carotid, is carried on by the anastomosis of the internal carotid with its fellow of the opposite side through the circle of Willis, by the vertebral with the opposite vertebral, by the inferior thyroid with the superior thyroid, by the deep cervical branch of the costocervical trunk with the descending branch of the occipital, by the superior thyroid, lingual, facial, occipital, and temporal arteries with their mates of the opposite side, and by the ophthalmic with the angular. The anastomosis between the deep cervical branch of the costocervical trunk with the descending branch of the occipital is an important one.[3]

Following its passage through the carotid canal in the petrous part of the temporal bone, the internal carotid artery passes through the entire length of the cavernous sinus which lies along the side of the sphenoid bone. This venous sinus occupies the interval between the endosteal and meningeal layers of the dura mater. In the posterior part of this interval lies the Gasserian ganglion. This venous space extends from the medial end of the sphenoidal fissure in front to the apex of the petrous bone behind. Its lateral wall contains the oculomotor and trochlear nerves and the ophthalmic division of the trigeminus, lying in this relation from above downward. In close contact with the internal carotid artery in its passage through the sinus lies the abducens nerve. These two structures are separated from the venous blood only by the endothelial lining of the sinus.[4]

The cavernous sinus is broken up into many endothelial-lined, intercommunicating compartments by numerous trabeculae. Anteriorly it receives the ophthalmic vein, with which it is practically continuous, and the sphenoparietal sinus. Communication with its fellow on the other side is effected through the small anterior and posterior intercavernous sinuses which cross the midline before and behind the hypophysis. Posteriorly it ends in the superior and inferior petrosal sinuses. The sphenoid bone inferio-medially provides the sinus with its only bony relationship.[4]

When a communication develops between the artery and the sinus there is a disruption of the local arterial and venous blood pressures. The ophthalmic vein, in addition to its normal venous load, is forced to receive arterial blood under high pressure from the internal carotid artery. The intersinus communications being unable to cope with the increased volume of blood, the sinus and the ophthalmic vein with its tributaries become dilated. As a result of this dilatation and the engorgement of the soft tissues of the orbit, there develops an exophthalmos and a pulsating swelling behind the medial angular process of the frontal bone. The passage of arterial blood through the abnormal channel may be heard as a rushing bruit when the stethescope is placed over the orbit or temporal region. The loss of vision and the ophthalmoplegia may be explained by injury to the optic, oculomotor, trochlear, and abducens nerves. This injury may be effected by the original trauma, by the dilatation of the sinus in whose lateral wall most of these nerves lie, by impaired nutrition, by pressure, or by the stretching induced by the proptosed eyeball.

The following describes a case of arteriovenous fistula involving the internal carotid artery and the cavernous sinus.

*Read in abstract before the Minnesota Academy of Ophthalmology and Otolaryngology, December 13, 1940.

The patient is a young married man, thirty years old, and in good general physical condition. He was first seen on May 9, 1940, five days after being struck by a fist over the left temporal region, a blow which stunned him momentarily but which did not cause unconsciousness. His first complaint was double vision, appearing almost immediately following the injury and progressing daily.

At the time of his first visit his complaints were double vision, pain through the left eye radiating to the back of the head, and intermittent slight nosebleeds from the left nostril. Examination revealed a normal appearing left eye with no congestion, proptosis, or hypertension. Vision was 6/6-3 and the eyegrounds were normal. The Maddox rod test showed an esophoria of nine degrees. The nasal bleeding was found to be caused by an ulceration in Kisselbach's area of the septum. A temporary diagnosis of paresis of the left external rectus muscle following a cerebral concussion was made. The septum was cauterized and the left eye was covered with a pad.

On May 14, five days later, the patient was seen again. He complained of increased pain in and about the left eye and described a swishing noise in the region of the left ear when in a recumbent position. A moderate proptosis had developed and a slight nystagmus was noted. Vision had dropped to 6/7-3 but the eyegrounds were still normal. No bruit was discernible with the stethescope. The patient was asked to return in three days, but he was not seen until a month later. During this interval he had been taking chiropractic treatments. By this time the picture had changed considerably. Proptosis of the eyeball was now very pronounced, although the eye could be pressed in to present an almost normal appearance. It would recede spontaneously at times, according to the patient. The eyeball was completely immobile due to a complete paralysis of all of the extrinsic ocular muscles, including the levator. Vision was found to be less than 6/120 but the eyegrounds were still normal. The swishing noise heard by the patient had increased and was more pronounced when the eye was bulging and when he was lying down. On this occasion a loud rushing bruit synchronous with the heart beat could be heard with the stethescope placed over the eyeball and over the left temporal region. The bruit could be made to disappear by pressure over the left common carotid artery. The blood Wassermann was found to be negative. A diagnosis was then made of an arteriovenous fistula involving the internal carotid artery and the cavernous sinue. An x-ray examination disclosed no evidence of skull fracture but did show an abnormality in the formation of the left optic foramen and of the left sphenoid fissure, these changes possibly being due to erosion by an impinging aneurysm or tumor.

At the suggestion of Dr. William Peyton of the University surgical staff daily digital compression of the common carotid artery was begun. This was done to stimulate the establishment of collateral circulation as preparation for carotid ligation. Whereas the patient could tolerate the procedure but a few minutes at first, he could stand thirty-five minutes of compression at the end of three weeks. During this period the proptosis increased and the entire left side of his face became swollen. The bruit became more pronounced and all subjective symptoms increased in severity.

On July 2, two months after the accident, a ligation of the left internal carotid artery was done under intratracheal anesthesia. This resulted in a slight lessening of the symptoms and an alteration in the quality of the bruit but did not cause it to disappear. Nor was the proptosis affected. However, the conjunctiva became severely edematous. Ten days later the neck was again entered and the common carotid ligated. Immediately the bruit ceased and the head noises and headache disappeared. Six days later the patient was able to leave the hospital. At this time his vision enabled him to count fingers at five feet. The eyeball had returned to its normal position in the orbit but was immobile. The upper lid was flaccid.

Vision rapidly returned. Within four weeks after operation the patient read 6/21+2. In another month his vision had improved to 6/12—2 and in one more month to 6/9—1 where it has remained. The return of muscle action has been extremely slow. No ocular motion was discernible until seven weeks following operation. At this time slight motion down and out was observed. At the ten-week stage motion up was noticed, and at the end of thirteen weeks some motion in all directions and the first noticeable lid movement was present. Since this time improvement in motion of the eye and lid has progressed slowly and continues to improve so. At the present date, twenty-six weeks following ligation, motion of the eyeball is estimated roughly at 25 per cent and motion of the lid at 75 per cent of normal.

With the advent of cold weather and probably due to incomplete closure of the lids the patient developed a large corneal ulcer which was extremely difficult to bring under control.

LEIOMYOMA OF THE UTERUS COMPLICATING PREGNANCY

W. L. PALMER, M.D., F.A.C.S., and HARRY B. NEEL, M.D.
Albert Lea, Minnesota

LEIOMYOMATA uteri, or uterine fibroids, are the most common abdominal tumor encountered by the general surgeon. A knowledge of their pathology and an understanding of the proper methods of diagnosing and treating them constitute a large portion of the armamentarium of the gynecologic surgeon.

The association of uterine fibroids with sterility has long been observed but it has not been established that fibroids cause infertility. In fact, fibroids constitute one of the most common complications of pregnancy. In pregnancy some of the fibroids move upward with the growing uterus and assume a position in the abdomen while others, such as cervical fibroids, remain in the pelvis. As the pregnant uterus enlarges and its wall becomes thin, tumors which were not detectable before pregnancy become prominent and are easily palpable through the abdominal wall. Not only are the fibroids made more conspicuous by their altered position, but they actually engage in the succulence and hypertrophy characteristic of pregnancy. It is said that they are

stimulated by the rich blood supply of the pregnant uterus.

The type of complication caused by a fibroid during pregnancy depends upon several factors. A tumor high in the uterus is more likely to produce abortion or premature labor than a cervical fibroid, while the latter may obstruct descent and delivery of the child. Submucous fibroids have a greater tendency to produce abortion than interstitial and subserous fibroids. Pedunculated fibroids may become twisted on their pedicles and cause excruciating pain. Such an accident may lead to gangrene of the tumor and abortion. Rupture of the uterine wall is one of the most serious catastrophies to which uterine fibroids are said to predispose.

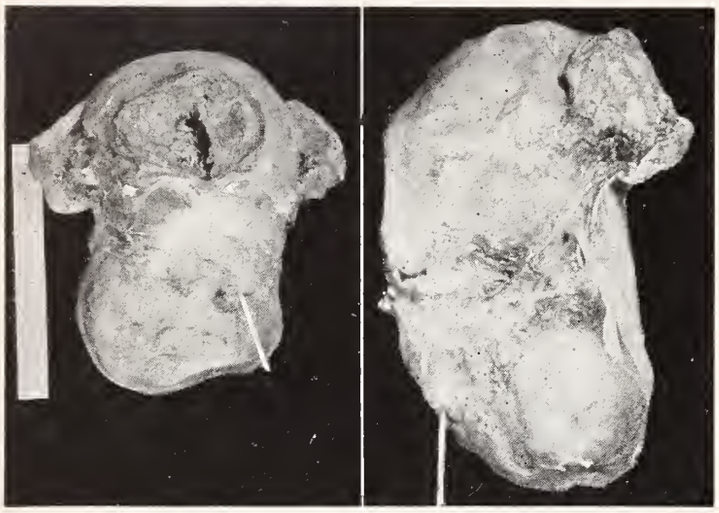

Fig. 1. (*left*) Anterior-posterior view of the surgical specimen. The upper half comprises the puerperal uterus with the incision through which the child was extracted. The lower half of the specimen is the cervical fibroid. A probe protrudes from the cervical canal. The molding of the tumor is obvious.

Fig. 2. (*right*) Lateral view of the uterus and fibroid. It is readily seen that the fibroid is nearly as large as the contracted uterus and that its shape conforms to the configuration of the pelvis.

The management of uterine fibroids usually presents no great difficulty but in exceptional cases the judgment and skill of the surgeon are taxed. Especially in pregnancy is it difficult to determine the safest procedure, the one that offers the best chance of survival to both mother and child. There are some who advocate myomectomy early in pregnancy. It is hardly justifiable to make this procedure a routine because many pregnancies are not disturbed by the small fibroids in the uterine wall, and the operative procedure may produce abortion. If the fibroid is large and it seems reasonable that pregnancy might be interfered with by its presence, surgical removal of the tumor is indicated. The patient should be informed that surgical intervention, although indicated, is occasionally followed by premature labor.

Even in those cases in which delivery is effected successfully in the presence of a fibroid the possibility of a complication has not been avoided. During the puerperium, fibroids will delay involution of the uterus and may obstruct the lochial flow. DeLee has said that they predispose to thrombophlebitis and infection. The sudden diminution of the blood supply to a fibroid after parturition may lead to degeneration of the tumor. Titus stated that this is the complication most frequently encountered.

In many instances it is advisable to postpone operative intervention until term, or near term, when the prospects of a viable child are good. Cesarean section can then be performed and the fibroid dealt with in the best possible manner. If the patient is elderly and has other children, hysteromyomectomy is the procedure of choice. If the patient is young and desires more children every effort should be made to save the uterus.

A patient recently referred by Dr. L. Hanson, of Frost, Minn., presented some of the difficulties encountered in pregnancy complicated by a large fibroid.

The patient was a secundi-gravida, thirty-one years of age. The family history and past history were essentially negative. The one child had been delivered normally nine years ago but the patient was said to have had a severe laceration. The date of the last menstrual period was February 8, 1940. The patient did not consult a physician for prenatal care.

Early on September 19, 1940, the patient *fell* into labor and the membranes ruptured soon thereafter. She consulted her physician and was examined. The fundus of the uterus was just below the xiphoid. The fetal parts were palpable on the right side and the fetal heart was audible in the left lower quadrant of the mother's abdomen. There was a ballotable mass just above the symphysis pubis but on rectal examination there was found a large mass which filled the pelvis and seemed to be the fetal head. The cervix was not identified. Although the uterine contractions were strong and frequent, there was no change in the findings after several hours. The patient was admitted to the Næve Hospital. She was again examined and the impression was that a large pelvic tumor obstructed the descent of the child. Cesarean section was decided upon.

Under nitrous oxide, oxygen and ether anesthesia a low mid-line incision was made. The uterus was symmetrically enlarged and the entire pelvis was filled with a large tumor, the consistency of which was similar to that of a fetal head. It arose from the posterior aspect of the cervix. An incision was made into the uterus and a live male baby which weighed three pounds, ten ounces, was delivered at 7:25 p. m. The position and size of the tumor made it impossible to do a myomectomy and preserve the uterus, so removal of the tumor and subtotal hysterectomy were indicated and performed. The fibroid had been so well molded into the pelvis that it was difficult to extract it and when it was finally removed there was a noise like that produced when a cork is quickly withdrawn from a bottle. The pelvis was peritonealized and the abdomen closed in the usual manner. The patient left the operating room in good condition.

The fixed specimen measures 19.5x13x12 cm. The contracted uterus and the tumor are approximately the same size as is demonstrated in Figures 1 and 2. Microscopic sections of the tumor reveal the typical picture of leiomyoma.

The patient made an uneventful convalescence and the infant gained weight rapidly.

NOTE: We wish to express our indebtedness to Dr. E. S. Palmerton for the illustrations accompanying this article.

HISTORY OF MEDICINE IN BROWN COUNTY

Compiled by George B. Weiser, M.D.

(Continued from May issue.)

Later Physicians in New Ulm

Dr. Theodore F. Hammermeister was born in Eden township, Brown County, near Morgan, Minnesota, July 25, 1887. He graduated from the University of Minnesota, Bachelor of Science, 1913; Doctor of Medicine, 1915, and served his internship at Northwestern Hospital, and Elliott Hospital, University of Minnesota.

Dr. Hammermeister located in New Ulm June 15, 1915, and has been in continuous practice there to date (1940). During his first four years he was associated with Dr. O. C. Strickler. He has been health officer of New Ulm since 1937; president of the local Board of Education for the past seven years. He is a member of the Redwood-Brown County Society, the Southern Minnesota Medical Association and the American Medical Association. He took postgraduate work at New York Polyclinic Medical School, the New York Postgraduate School, and in the Laboratory of Surgical Technique, Chicago, Illinois.

Dr. A. L. Kusske was born in Sibley County, June 24, 1894. He graduated from the University Medical School in 1907, and was located at Hutchinson, Minnesota, from 1911 to 1916. He took a postgraduate course at Illinois Eye and Ear Infirmary and then located in Minneapolis, 1918 to 1924. He was assistant in the Eye Department of University of Minnesota Medical School from 1918 to 1924.

He moved to New Ulm in 1924 and has practiced there continuously to present time (1940). He confines his practice to his specialty, eye and ear diseases.

Dr. F. J. Pelant was born in Montgomery, Minnesota, July 31, 1886. He received his preliminary education at St. Thomas College and Saint Paul Seminary and graduated in medicine at the College of Medicine and Surgery, Chicago, in 1916. He served his internship at St. John's Hospital, Springfield, Illinois, and did postgraduate work at the New York Polyclinic in 1916. After graduation he practiced for a brief period in Iowa before coming to New Ulm.

Dr. Frederick H. Dubbe was born at Jordan, Minnesota, April 27, 1895. He attended high school at Jordan and Carleton College, 1912-1913, before attending the University of Minnesota, where he received the B.S. degree in 1915. He graduated from the University of Minnesota Medical School in 1919 and served his internship at the Minneapolis General Hospital, 1919-1920.

On June 1, 1920, Dr. Dubbe located in New Ulm where he has been in continuous practice to the present time (1940). He is a member of the Redwood-

Brown County Society, the Southern Minnesota and State Medical Associations and the American Medical Association, and a fellow of the American College of Surgeons. He is local surgeon for the Chicago & Northwestern and Minneapolis & St. Louis Railroads and a member of the American Railway Medical Society.

Dr. Clifford T. Ekelund was born in Saint Paul, Minnesota, December 7, 1893. He received his B.S. and M.D. degrees at the University of Minnesota Medical School. During the World War he served in a base hospital in France until March, 1919, followed by an interlude of eighteen months with the American Expedition to Poland, organizing, doing surgery, etc.

Returning from the war he became a teaching fellow in the Graduate School of Medicine at the University of Minnesota and was chief resident in medicine at the Minneapolis General Hospital. The following year he became chief resident in surgery at the University Hospital for two years. From January 1, 1923, to July 1, 1923, he was associated with Dr. T. F. Hammermeister at New Ulm. In July, 1923, he became a member on the staff of Rood Hospital, Hibbing, Minnesota, remaining there three years; then moved to Pontiac, Michigan, where he has been continuously engaged in the practice of medicine and surgery. He was elected for the term of one year as secretary of the Michigan State Medical Society.

Dr. Albert Fritsche was born in New Ulm January 31, 1893. He graduated from the New Ulm high school in 1911, attended the University of Wisconsin as a pre-medical student, 1911-1913, attended the University of Wisconsin Medical School, 1914-1917, and graduated from the Chicago College of Medicine and Surgery, Loyola Seminary, in 1918. He served his internship in the Norwegian-American Hospital, also Asbury Hospital, Minneapolis.

He became associated with his father, Dr. L. A. Fritsche, in the Fritsche Clinic, in 1919 and has continued there to the present time (1940), specializing in surgery. He was a member of the Medical Reserve Corps in active duty, 1917-1918; vice president of the Minnesota State Medical Association, 1940; and is a past president of the Southern Minnesota Medical Association. He is a Director of the Citizens State Bank of New Ulm and the New Ulm Roller Mill Company.

Dr. William Henry Fritsche, son of Dr. L. A. Fritsche, was born March 20, 1895. He graduated from the New Ulm high school, 1913; attended the University of Minnesota, 1915-1916; graduated from Marquette Medical School, 1919; served his internship in the New York Lying-in Hospital. Beginning October, 1919, he was associated with the Fritsche Clinic until his death in 1923.

Dr. F. D. Hurd, a graduate of University of Minnesota Medical School, first located at Hibbing, then came to New Ulm in 1926. He was associated with the Fritsche Clinic for six months, then moved to Great Falls, Montana.

Dr. Carl John Fritsche was born at New Ulm January 14, 1904. He graduated from the New Ulm high school, attended the University of Wisconsin, 1922-1924; University of Minnesota, 1924-1926; Northwestern University Medical School, Chicago, 1929, and served his internships at the Norwegian-American Hospital, Chicago, 1930, and the McCormack Institute of Infectious Diseases,

1929. He located in New Ulm in January, 1930, and has been associated to present date (1940) with the Fritsche Clinic. He was commissioned First Lieutenant in the Medical Reserve Corps in 1932.

Dr. Theodore R. Fritsche was born in New Ulm October 23, 1906. He attended the New Ulm high school and graduated from the University of Minnesota, B.S. degree, 1928. He graduated from the University of Minnesota Medical School in 1931 and served his internship at Letterman General Hospital, U. S. Army, San Francisco, 1930-1931. He had a Fellowship in the Illinois Charitable Eye and Ear Infirmary, 1931-1933, and the Ancker Hospital, Saint Paul, 1933-1934.

Dr. Fritsche located in New Ulm in October, 1935, being associated with the Fritsche Clinic. He received degrees from the American Board of Ophthalmology, 1937, and the American Board of Otolaryngology, 1938, and is a fellow of the Academy of Ophthalmology and American College of Surgeons, of which he was second vice president in 1940.

Dr. Cornelius A. Saffert, born January 12, 1903, received his high school education in New Ulm and at St. Thomas Military Academy, Saint Paul. He entered the University of Minnesota in 1921 and received his B.S. degree in 1923; medical degree in 1926. He served his internship at the Minneapolis General Hospital from 1924 to 1926.

Dr. Saffert located at New Ulm August 1, 1926, and has been associated with Dr. T. F. Hammermeister there to present time (1940). He was health officer for New Ulm from 1934 to 1937.

Dr. L. A. Weissgeber, a graduate of the University Medical School, Toronto, Canada, was associated with the Vogel and Seifert Clinic during the year 1928. He then moved to Northwest Canada.

Dr. Fred H. Wiechman, a graduate of the University of Minnesota Medical School, 1930, located in New Ulm in 1930, then the latter part of that year moved to Sleepy Eye where he engaged in the practice of medicine until 1935; thence to Fort Meade, South Dakota. Dr. Wiechman located in New Prague, Minnesota, in 1939.

Dr. Howard A. Vogel, a native of New Ulm, born February 2, 1907, graduated from the University of Minnesota in 1930. He took his premedical course at the University, then served on a rotating service at Detroit Hospital for eighteen months. He served an internship at Abbott Hospital for two years while attending the University of Minnesota; had a fellowship in medicine at the University of Minnesota for two years, and attended medical clinics in Europe. He located in New Ulm July, 1932, and has continued to practice there since that time.

Dr. O. B. Fesenmaier, born in New Ulm, September 23, 1907, was educated in New Ulm high school. He graduated from the Marquette Medical School in 1936, and served his internship at St. Ann's Hospital. He located in New Ulm the year of his graduation. He is the present secretary of the Redwood-Brown Medical Society.

Correction.—The name of the physician appearing at the end of page 257 of the April issue should be Dr. W. G. Nuessle, instead of Muessle, as printed.

HOMEOPATHIC AND ECLECTIC MEDICINE IN MINNESOTA*

By James Eckman†

Rochester, Minnesota

HOMŒOPATHIC PHYSICIAN.—*A Homœopathic Physician is one who adds to his knowledge of Medicine a special knowledge of Homœopathic Therapeutics and observes the Law of Similia.* All that pertains to the great field of medical learning is his, by tradition, by inheritance, by right. EUGENE H. PORTER, M.D.—Transactions of the American Institute of Homœopathy, 1889, pp. 57, 102.

DURING the passage of some seventy years since Minnesota emerged from what might be called a frontier status, the contributions of homeopathy and homeopathic practitioners of medicine to the state have been largely forgotten. Yet homeopathy and its apostles played an important part in the history of Minnesota, not because the system of medicine itself was important, but because in many pioneer communities in the early years of the state the only physicians available were homeopaths. Moreover, a most provocative parallel could be formed if the gradual development and ascent of homeopathy in the United States were compared to the slow transition of the Territory of Minnesota from a status of virtual isolation to its emergence as a powerful and very nearly self-sufficient unit of the Federal Union. In chronologic aspects, the rise of homeopathy in the United States would be strikingly similar to the evolution of Minnesota as a state.

To the body of homeopathic practitioners of medicine who helped to found medical practice in Minnesota should be added the lesser body of eclectic physicians, many of whom were graduates of medical colleges, others of whom were merely herbalists of purely local renown, "steam doctors," physio-medical healers, naturopathic physicians and mechano-medical practitioners. Men such as these, who ventured into frontier homes and ministered to pioneer settlements from one end of the state to the other, were as necessary to the stricken prairie multitudes as were the well-trained metropolitan physicians and surgeons to their patients. Homeopathy and eclecticism contributed only a little to the great corpus of medicine as it is practiced today; both systems of practice were already senescent when the Twentieth Century began. Yet the practitioners who, however mistakenly, embraced and practiced homeopathy or eclecticism in the fifties, sixties and seventies in Minnesota were as truly pioneers as the men who came out from New England and the Atlantic Seaboard—from Harvard College, Yale College, the University of Pennsylvania, and other famous schools of medicine of the time—to settle in the somber and wildly beautiful reaches of a state in which the fearsome savage still roamed the bleak tundras and the deer and brown bear did not yet fear to show themselves near the outskirts of the frontier hamlets of forest and plain.

No consideration of either the virtues or the faults of homeopathy will be made in this paper; first, because the author is not qualified to do so; second, because such a consideration would have but very little validity if it were intruded into a study such as the present one. For the sake of historical per-

*This study includes ancillary, and not essential, data in extended form which have been collated for a work in progress that is to be submitted to the Graduate School of the University of Minnesota, under the guidance of Richard E. Scammon, Ph.D., LL.D. This study does not represent either the final form or the final content of the aforementioned work.

†Division of Publications, Mayo Clinic.

spective, part of a paragraph by Fishbein[1] may be offered without affirmation or rejection of its conclusion:

> . . . . the influence of Hahnemann was, on the whole, certainly for the good. He emphasized the individualization of the patient in the handling of disease, he stopped the progress of half a dozen or more peculiar systems of treatment based on a false pathology, and he demonstrated the value of testing the actual virtues of drugs by trial. It is probably true that any criticisms which might be brought against him in the light of later and better knowledge apply equally well against a large part of the other medicine of his time.

More recently (1940), Guttentag[2] has suggested that homeopathy actually is "an integral part of the divisions of clinical medicine on the one hand and of pharmacology on the other." Guttentag also professed to have encountered instances of the increasing acceptance of homeopathic doctrines in contemporary medical practice.

The Minnesota State Homœopathic Institute

Organization of the Minnesota State Homœopathic Institute* in 1867 would appear to antedate formation of the Minnesota State Medical Society,† the *Transactions* of which are dated from the year 1870. But Armstrong[3] has shown that the Minnesota State Medical Society actually had been organized on July 23, 1853, and that it was *reorganized* on February 1, 1869, in Saint Paul. Dr. John H. Murphy (1826-1894) is known to have attended the seventh session of the American Medical Association at Saint Louis in May, 1854, as a delegate from the "Minnesota Medical Society,"[4] a circumstance which attests to the existence of an early "regular" medical society in Minnesota antedating the one which was said to have been "organized" in 1869.

The American Institute of Homœopathy is, however, older than the American Medical Association. It was founded in New York City in 1844,[5] whereas the American Medical Association was not founded until 1847.

An unidentified homeopathic physician[6] (probably Dr. William E. Leonard) has written of the Minnesota homeopathic organization:

> Accordingly, at the "Globe Hotel," on the corner of Minnesota and Second streets in Saint Paul, these brethren of a persecuted faith met Feb. 14, 1867. This place was historical, for here had assembled the first legislature; and indeed, all prominent State enterprises in those early days had here their beginnings.

Sixteen homeopathic practitioners drew up the articles of federation for the institute, and these sixteen practitioners in later days came to be recognized by Minnesota homeopaths as the "sixteen apostles." It is not probable that there were many more than sixteen homeopathic physicians in Minnesota in 1867, for it was written that: "In the spring of 1867, the Homœopathists of Minnesota could count their brethren on their fingers."[6]

The sixteen homeopaths who signed the Articles of Association at the old Globe Hotel in Saint Paul were John Nutting Wheat, M.D. (1818-1903), of Minneapolis; E. Cooley, M.D., of Faribault; Charles Draper Williams, M.D. (1812-1882), of Saint Paul; E. A. Boyd, M.D. (1817-1888), of Saint Paul;

*The diphthong *œ*, which in English reproduces the Latin spelling of the Greek combination of *omicron* and *iota*, was employed uniformly by homeopaths in almost all their literature. It has been retained in this study of official titles and in quoted material, but not in the text. It is interesting to note that Hahnemann himself used the expression *homöopathie*, and that the sententious *Edinburgh Review* (volume 50, pages 507 and 513) in 1830 repeated this Germanic form in preference to the English approximation of the Greek compound.

†The name "Minnesota State Medical Association" was not assumed until 1902, when the state medical organization was reorganized in accordance with the recommendations of the American Medical Association.

T. N. Berlin, M.D. (1823-1911), of Farmington; Z. B. Nichols, M.D., of Faribault; T. Romeyn Huntington, M.D. (1829-1873), of Minneapolis; D. S. French (1812-1867), of Shakopee; Heinrich von Wedelstaedt, M.D. (1817-1900), of Saint Paul; William Caine, M.D. (1819-1867), of Stillwater; William Huntington Leonard, M.D. (1825-1907), of Minneapolis; Edward S. Warner M.D.; Philo L. Hatch, M.D. (1823-1904), of Minneapolis; William A. Penniman M.D. (1802-1872), of Minneapolis; Thomas Chatterton Schell, M.D. (1823-1883), of Saint Paul; and Sidney R. Wakefield, M.D. (1822-1916), of Monticello.[6]

Articles of Association for the Institute were filed in the office of the register of deeds of Ramsey County in Saint Paul on February 15, 1867. They were recorded by Jacob Mainzer (1834-1893), register of deeds, in "Book 'A' of incorporations, page 107."[7] On the same date Secretary of State Henry C. Rogers (1834-1871) announced that the Articles of Association for the Institute had been filed in his office "according to law."[7]
